

## COMBINED INDICES OF ABUNDANCE OF BLUE SHARKS IN THE NORTH AND SOUTH ATLANTIC OCEAN

Enric Cortés<sup>1</sup>

### SUMMARY

*Indices of relative abundance (CPUEs) available for the stock assessments of blue shark (*Prionace glauca*) in the North Atlantic and South Atlantic Ocean were combined using different methods. Following the work conducted for the 2008 SCRS blue shark stock assessment, indices were combined through a GLM with two choices of weighting: by the catch of the flag represented by each index and by the area of the flag represented by each index. Additionally, a hierarchical index of abundance that combines all available indices into a single series was also developed. The three indices obtained for the North Atlantic and South Atlantic generally followed very similar trends, with a flat tendency in the North Atlantic and an increasing trend in the South Atlantic. These indices can potentially be used in sensitivity analyses in the stock assessments.*

### RÉSUMÉ

*Les indices d'abondance relative (CPUE) disponibles pour les évaluations de stocks de requin peau bleue (*Prionace glauca*) de l'Atlantique Nord et Sud ont été combinés au moyen de différentes méthodes. Conformément aux travaux réalisés pour l'évaluation du stock de requin peau bleue de 2008, les indices ont été combinés au moyen d'un GLM avec deux choix de pondération : par la prise du pavillon représentée par chaque indice et par la zone du pavillon représentée par chaque indice. De plus, un indice hiérarchique d'abondance combinant tous les indices disponibles dans une seule série a également été créé. Les trois indices obtenus pour l'Atlantique Nord et l'Atlantique Sud affichaient généralement des tendances très similaires, avec une tendance aplatie dans l'Atlantique Nord et une tendance ascendante dans l'Atlantique Sud. Ces indices peuvent éventuellement être utilisés dans des analyses de sensibilité dans les évaluations de stocks.*

### RESUMEN

*Los índices de abundancia relativa (CPUE) disponibles para las evaluaciones de stock de tintorera (*Prionace glauca*) en el Atlántico norte y el Atlántico sur se combinaron utilizando diferentes métodos. Tras el trabajo realizado para la evaluación del stock de tintorera del SCRS de 2008, se combinaron los índices mediante un GLM con dos opciones de ponderación: por la captura del pabellón representado por cada índice y por el área del pabellón representado por cada índice. Además, se desarrolló también un índice de abundancia jerárquico que combina todos los índices disponibles en una serie única. Los tres índices obtenidos para el Atlántico norte y sur seguían en general tendencias muy similares, con una tendencia plana en el Atlántico norte y una tendencia ascendente en el Atlántico sur en los años recientes de la serie temporal. Estos índices pueden ser potencialmente utilizados en análisis de sensibilidad en las evaluaciones de stock.*

### KEYWORDS

*Time series analysis, stock assessment, abundance, fishing effort, catch statistics, shark fisheries, pelagic fisheries, blue shark*

## 1. Introduction

In the 2008 Blue Shark and Shortfin Mako Stock Assessment meeting, the Working Group decided to develop combined indices as overall indicators of relative abundance (Anon. 2009). The indices available at the time were combined through a GLM approach using two choices of weighting: by area fished and by catch. Following that approach, combined abundance indices were generated for the North and South Atlantic using both area fished (using hooks as a proxy) and catch series developed at the 2015 Blue Shark Data Preparatory meeting (Anon. 2015 (*in press*)). Additionally, a hierarchical index was also developed for the North and South Atlantic that combines all the available CPUEs into a single time series (Conn 2010). The rationale for using this method is that the individual indices attempt to estimate relative abundance but are subject to both sampling and process error. While sampling error is assumed to be captured by previous (GLM) standardization of the indices through the CVs, each index is also subject to process variation, which describes the degree to which a given index measures “artifacts” above and beyond abundance in the population. As a whole, all these combined indices have the advantage of providing a single signal to the stock assessment model and can be used in sensitivity analyses if deemed adequate by the Working Group.

## 2. Materials and methods

### 2.1 Data

Annual weights for the CPUE series were computed using catch by flag (method 1) or area fished (method 2). To calculate area, the most recent 5x5 degree data on longline hooks prepared by the Subcommittee on Ecosystems (P. de Bruyn, pers. comm..), which included data up to 2009, were used. Values for 2010-2013 were assumed to be the mean of the last five years of data (2005-2009). Annual weights were then computed as follows: first, annual catches or effort of the flags represented by CPUE series (Tables 6 and 7 of the 2015 Blue Shark Data Preparatory meeting) were expressed as proportions, then for each flag, if the year for which catch (effort) was available also had an index value (Table 8 of the 2015 Blue Shark Data Preparatory meeting), the catch (effort) was expressed as a proportion of the total, which summed to 1. Annual weights based on catch and area for each of the CPUE series considered for the North Atlantic and South Atlantic stock assessments are included in **Table 1** and **Table 2**. Additionally, annual index values with the associated CVs were used in the hierarchical analysis of CPUEs (method 3). All values used are listed in **Table 3** (indices) and **Table 4** (CVs used in method 3).

### 2.2 Analysis

For methods 1 and 2, relative abundance indices were estimated using a Generalized Linear Modeling (GLM) approach assuming a normal distribution (identity link) on log-transformed catch rates and applying a back-transformed log bias correction. Year and CPUE series were explanatory variables and the weights computed above were used to weight the GLM. For method 3, relative abundance indices were computed using a Bayesian approach (see Conn 2010 for details).

## 3. Results and discussion

The three methods yielded similar time trajectories of relative abundance (**Figure 1**). For the North Atlantic all trajectories followed the same general trend, with the noticeable exception of a dip for the effort-weighted index in 2002, but despite fluctuations the series were relatively stable over the entire time trajectory (**Figure 1 top**). For the South Atlantic, the effort-weighted index showed more extreme fluctuations, especially in the latter part of the time series, and all series showed an accentuated increasing tendency since the mid-1990s (**Figure 1 bottom**). The individual indices for the North Atlantic are summarized in **Table 5** and those for the South Atlantic in **Table 6**.
