# REPORT OF THE STANDING COMMITTEE ON RESEARCH AND STATISTICS (SCRS) 

(Madrid, Spain, October 4-8, 2010)

## REPORT OF THE STANDING COMMITTEE OF RESEARCH AND STATISTICS

(Madrid, Spain, October 4-8, 2010)

## TABLE OF CONTENTS

1. Opening of the meeting ..... 1
2. Adoption of Agenda and arrangements for the meeting ..... 1
3. Introduction of Contracting Party delegations ..... 1
4. Introduction and admission of observers ..... 1
5. Admission of scientific documents ..... 2
6. Report of Secretariat activities in research and statistics ..... 2
7. Review of national fisheries and research programs ..... 2
8. Executive Summaries on species: ..... 11
YFT-Yellowfin ..... 12
BET-Bigeye ..... 27
SKJ-Skipjack ..... 43
ALB-Albacore ..... 58
BFT-East-Med ..... 75
BFT-West ..... 81
BUM/WHM-Blue marlin/White marlin ..... 100
SAI-Sailfish ..... 112
SWO-ATL-Swordfish ..... 120
SWO-MED-Swordfish ..... 139
SBF-Southern Bluefin ..... 148
SMT-Small Tunas ..... 149
SHK-Sharks ..... 163
9. Report of Inter-sessional meetings ..... 181
9.1 Working Group on Stock Assessment Methods ..... 181
9.2 Bigeye Tuna Data Preparatory Meeting ..... 181
9.3 Blue Marlin Data Preparatory Meeting ..... 181
9.4 Inter-sessional Meeting of the Sub-Committee on Ecosystems ..... 182
9.5 Mediterranean Swordfish Stock Assessment Session ..... 182
9.6 Mediterranean Albacore Data Preparatory Meeting ..... 182
9.7 Bigeye Tuna Stock Assessment Session ..... 183
9.8 Bluefin Tuna Data Preparatory Meeting ..... 183
9.9 Bluefin Tuna Stock Assessment Session ..... 183
10. Report of Special Research Programs ..... 183
10.1 Atlantic-wide Research Programme for Bluefin Tuna (GBYP) ..... 183
10.2 Enhanced Research Program for Billfish ..... 184
11. Report of the Sub-Committee on Statistics ..... 184
12. Report of the Sub-Committee on Ecosystems ..... 184
13. Consideration of implications of the Tuna RFMOs workshops held in 2010 in Barcelona and Brisbane ..... 184
13.1 Joint Tuna RFMOs Meeting of Experts to Share Best Practices on the Provision of Scientific Advice ..... 184
13.2 Joint Tuna RFMOs Meeting of Experts on Tuna RFMO Management Issues Relating to by-catch ..... 186
14. Consideration of plans for future activities ..... 187
14.1Annual Work Plans ..... 187
14.2Inter-sessional meetings proposed for 2011 ..... 187
14.3Date and place of the next meeting of the SCRS ..... 187
15. General recommendations to the Commission ..... 189
15.1 General recommendations to the Commission that have financial implications ..... 189
15.2 Other recommendations ..... 190
16. Responses to Commission's requests ..... 191
16.1 Defining a standardized methodology for the collection of sport and recreational fisheries data for all species under ICCAT mandate, including estimates of post- release mortality and data from sampling, tagging and counting programs ..... 191
16.2 Continuation of the evaluation of data elements pursuant to Rec. 05-09 ..... 192
16.3 Identify as precisely as possible BFT spawning grounds in the Mediterranean in View of the creation of sanctuaries Rec. 08-05 ..... 193
16.4 Review of information on farmed bluefin tuna growth rates Rec. 06-07 and 08-05 ..... 194
16.5 Review of data availability on the interaction of tuna fisheries on seabirds and sea turtles ..... 195
16.6 Review of Ghana's action plan to strengthen the collection of statistical data ..... 195
16.7 Evaluation of the effect of the closure contained in [Rec. 08-01] and alternative closures ..... 196
16.8 Reporting on the bluefin scientific data coverage level achieved by each Contracting Party observer program [Rec. 08-05] ..... 199
17. Other matters ..... 201
17.1 Continued Involvement with ISSF. ..... 201
18. Election of Chairman ..... 201
19. Adoption of the report and closure ..... 201
Appendix 1. SCRS Agenda ..... 202
Appendix 2. List of SCRS Participants ..... 204
Appendix 3. List of SCRS Documents ..... 214
Appendix 4. Opening Address by the Executive Secretary ..... 227
Appendix 5. 2011 Work Plans of Species Groups ..... 228
Appendix 6. Report of the Atlantic-wide Research Programme for Bluefin Tuna (GBYP) ..... 243
Appendix 7. ICCAT Enhanced Research Program for Billfish ..... 248
Appendix 8. Report of the Sub-Committee on Statistics ..... 253
Appendix 9. Report of the Sub-Committee on Ecosystems ..... 263
Appendix 10. Letters from ISSF referring to the use of their data ..... 265

# REPORT OF THE <br> STANDING COMMITTEE ON RESEARCH AND STATISTICS (SCRS) 

$$
\text { (Madrid, Spain -October } 4 \text { to 8, 2010) }
$$

## 1. Opening of the meeting

The 2010 Meeting of the Standing Committee on Research and Statistics (SCRS) was opened on Monday, October 4 at the Hotel Velázquez in Madrid by Dr. Gerald Scott, Chairman of the Committee. Dr. Scott welcomed all the participants to the annual meeting.

The ICCAT Executive Secretary, Mr. Driss Meski, addressed the meeting and welcomed all the participants to Madrid. In his opening address, Mr. Meski expressed appreciation to the Kingdom of Spain for its valuable contributions to and collaboration with the Secretariat. The SCRS has a special mandate to ensure the recovery and sustainable exploitation of stocks, a task that is followed closely by fishery experts throughout the world. This means that ICCAT is considered one of the major Regional Fishery Management Organizations (RFMOs) in the world. The Executive Secretary's opening address is attached as Appendix 4.

## 2. Adoption of Agenda and arrangements for the meeting

The Tentative Agenda was reviewed and adopted (attached as Appendix 1). Stock assessments were carried out this year on bluefin tuna (BFT), bigeye tuna (BET), and Mediterranean swordfish (SWO-Med).

The following scientists served as rapporteurs of the various species sections (Agenda Item 8) of the 2010 SCRS Report.

| Tropical tunas- General | J. Pereira |
| :--- | :--- |
| YFT - Yellowfin tuna | C. Brown |
| BET - Bigeye tuna | D. Die |
| SKJ - Skipjack tuna | D. Gaertner |
| ALB - Albacore | V. Ortiz de Zarate |
| BFT - Bluefin tuna | C. Porch (W), J.M. Fromentin (E) |
| BIL - Billfishes | F. Arocha |
| SWO - Swordfish | J. Neilson, P. Travassos (Atl.), G. Tserpes (Med.) |
| SBF - Southern bluefin |  |
| SMT - Small tunas | J. Ortiz de Urbina |
| SHK - Sharks | A. Domingo |

The Secretariat served as rapporteur for all other Agenda items.

## 3. Introduction of Contracting Party delegations

The Executive Secretary introduced the 20 Contracting Parties present at the 2010 meeting: Angola, Brazil, Canada, Cape Verde, China, Côte d'Ivoire, Croatia, European Union, Ghana, Japan, Korea, Mauritania, Mexico, Morocco, Norway, Russian Federation, Senegal, United Kingdom (Overseas Territories), United States and Uruguay. The List of Participants at the Species Groups Meetings and the Plenary Sessions is attached as Appendix 2.

## 4. Introduction and admission of observers

Representatives from the following Cooperating Entity (Chinese Taipei), intergovernmental organizations (General Fisheries Commission for the Mediterranean-GFCM), and non-governmental organizations (Federation of Maltese Aquaculture Producers-FEAP, Greenpeace, International Seafood Sustainability Foundation-ISSF, The Pew Environmental Group, and World Wide Fund for Nature-WWF were admitted as observers and welcomed to the 2010 SCRS (see Appendix 2).

## 5. Admission of scientific documents

The Secretariat informed the Committee that 145 scientific papers had been submitted at the various 2010 intersessional meetings.

Besides the scientific documents, there are nine reports of inter-sessional meetings and Species Groups, 26 Annual Reports from the Contracting Parties, and non-Contracting Cooperating Parties, Entities and Fishing Entities, a report from CARICOM, as well as various documents by the Secretariat. The List of SCRS Documents is attached as Appendix 3.

## 6. Report of Secretariat activities in research and statistics

The Secretariat presented the "Secretariat Report on Statistics and Coordination of Research 2010" [SCI/008] which summarizes activities in 2010. This document was discussed at length during the Species Groups meetings and during the session of the Sub-Committee on Statistics. The first eight tables of this document point out the improvements in data submission and the use of the electronic forms. This report also notes the Secretariat's efforts to implement last year's recommendations from the SCRS concerning the purchase of computer hardware, software and WiFi internet equipment.

The report by the Secretariat also includes summary tables of the information available in the compliance-related databases, as requested by the Commission. In 2009, the SCRS requested the Commission's approval of a Data Confidentiality proposal (see Appendix 10 of the 2009 Biennal Report). The SCRS again requests the Commission's approval of the Data Confidentiality proposal and reiterates its importance for the purpose of use of detailed information at the Secretariat by the SCRS working groups.

The Executive Secretary informed the SCRS of the incorporation of Dr. Mauricio Ortiz and the permanent position of Mr. Alberto Parrilla to the Secretariat staff in 2010. He also noted that Dr. Antonio Di Natale was appointed Coordinator of the Atlantic-wide Bluefin Year Programme (GBYP), and Mr. Takahiro Ara as Coordinator of the ICCAT/Japan Project for the Improvement of Data and Management of Tuna Fisheries (JDMIP).

A summary of the activities carried out by the ICCAT/Japan Data and Management was presented (JDMIP) (SCI-009). This project continues to support port sampling developed in Tema (Ghana) and Abidjan (Côte d'Ivoire). This program has also made financial contributions towards the holding of training courses in Sao Tome and Senegal.

Likewise, the Secretariat informed of the activities carried out in 2010 in relation to publications.

## 7. Review of national fisheries and research programs

In accordance with the format established in 2005 and reviewed in 2007, only information relative to new research programs was presented to the Committee. The Committee considered the need to include information of interest for its work, separating it from the Annual Report which, with its current structure, is more geared to providing information to the Commission on compliance. The Committee reiterated the need to follow the guidelines established for the preparation of the Annual Reports and to try to clearly define the contents under the various sections (scientific or compliance).

## Angola

The major scombrid species caught in Angola are: yellowfin tuna (Thunnus albacares), skipjack tuna (Katsuwonus pelamis), bigeye tuna (Thunnus obesus), albacore (Thunnus alalunga) and small tunas, such as Atlantic black skipjack (Euthynnus alletteratus), Atlantic bonito (Sarda sarda), and frigate tuna (Auxis thazard). These resources are caught by the artisanal, semi-industrial and industrial fleet. Angola does not have any vessels for fishing directed at tunas. These are foreign flag vessels that fish in the Exclusive Economic area of Angolan waters. Therefore, Angola does not have any data to report to ICCAT on large tunas. In 2009, 54 foreign vessels reported catches of large tunas. The total catch of small tunas was about 3,669 tons ( t ) off the Antolan coast, of which 1,979 t were Sarda sarda, 1,644 t Euthynnus alletteratus, and 46 t Auxis thazard. These
catches are from the artisanal, semi-industrial and local industrial fleet. The gear types normally used for the target species are seine, trawl, baitboat, hand line, mainly trap, and also longline by the foreign vessels. The Institut National de Recherches de Pêches-INIP (National Institute on Fishing) through its Research Center at Lobito reinforces the sampling program through the collection of biological data, in particular, size frequency data on the major species of small tunas from the traps. In 2009, 22 samplings of small tunas were carried out with a total of 2,419 fish measures. The statistical data are obtained from the Direction Nationale de Pêche et Aquaculture-DNPA (National Directorate of Fishing and Aquaculture), the Cabinet d'Études de Plans et Statistiques-GEPE (Cabinet of Studies of Plans and Statistics), the Institut National de Recherches de PêchesINIP (National Institute on Fishing), the Centres de Recherches de Pêches-CIPs (Fisheries Research Centers), and the Institut de Pêches Artisanale-IPA (Institute of Artisanal Fishing).

## Brazil

In 2009, the Brazilian tuna longline fleet consisted of 86 vessels registered in 6 different ports. Of these, 80 were national and 6 were foreign chartered vessels. The number of vessels decreased by about $9.5 \%$ from 2008, when 95 vessels operated. The number of chartered vessels, however, decreased by about $33 \%$. The number of baitboats operating in 2009 was 43, increasing slightly (5\%) from 2008. These 43 vessels ( $100 \%$ national) were based in the same ports (Rio de Janeiro-RJ, Itajaí- SC, and Rio Grande-RS). In 2009, the number of purse seiner boats was 8 , remaining the same as in the previous year.

The Brazilian catch of tunas and tuna-like fish, including billfish, sharks, and other species, was about $40,000 \mathrm{t}$ (live weight), in 2009, representing an increase of about $12 \%$, from 2008. The majority of the catch again was taken by bait-boats, which accounted for about $60 \%$ of the catches, with skipjack tuna being the most abundant species, representing close to $95 \%$ of the bait-boat catches. Total catch of the tuna longline fishery was equal to 7,800 t, in 2009 , being thus about $15 \%$ smaller than in 2008, with swordfish being again the most abundant species, with a total catch close to 3.100 t . Blue shark, yellowfin tuna and bigeye tunas were the three most caught species, after the swordfish, accounting for about $16 \%(1,268 t), 13.5 \%(1,038 t)$ and $13 \%(1,008 t)$ of the total longline catches. The total catch of white marlin and blue marlin was 52 t and 149 t , respectively, which is similar to the 2008 levels ( 47 t and 161 t , respectively).

Part of the Brazilian catches continued to result from a small-scale fishing fleet based mainly in Itaipava, on the southeast coast. Although comprised of relatively small boats of about 15 m in total length, this fleet is highly mobile, operating throughout most of the Brazilian coast and targeting a variety of species with different gears, including longline, handline, trolling and other surface gears. The total catch of this fleet, which mainly targets dolphin fish, in 2009, was about $8,000 \mathrm{t}$, of which $4,372.2 \mathrm{t}(53 \%)$ was dolphinfish.

Several institutions directly assisted the Ministry of Fisheries and Aquaculture (MPA) in processing and analyzing data from the Brazilian tuna fishery in 2009. Besides the catch and effort data regularly collected in 2009, about 16,000 fish were measured at sea while landings included skipjack $=9,724$; swordfish $=2,109$; bigeye $=1,843$; yellowfin $=782$; blue shark $=596$; albacore $=179$; sailfish $=111$; blue marlin $=102$; and white marlin $=42$, among others.

In 2009, an important shark and billfish research effort, in cooperation with U.S., Venezuelan and Uruguayan scientists, continued to be developed, including the collection of vertebrae, spines, stomachs and gonads, for age and growth, feeding habits and reproduction studies, as well as habitat utilization, through PSAT tags, and gear selectivity, by the use of circle hooks, hook timers, and TDRs.

Research on the incidental catches of seabirds continued and was aimed mainly at monitoring by-catch and testing mitigation measures, particularly the use of different kinds of torilines. The monitoring of sea turtle bycatches in longline fisheries also continued by the "Projeto Tamar", including tests with the use of circle hooks and other mitigation measures to reduce the catch rates of sea turtles.

In order to adequately comply with ICCAT recommendations, the Brazilian government has implemented several rules regulating the Brazilian tuna fishery, although no new regulation was introduced in 2009. It is important to note, however, that in 2009 Brazil adopted a new law on fisheries and aquaculture and raised the Secretariat of Fisheries and Aquaculture to the level of Ministry.

## Canada

Bluefin tuna are harvested in Canadian waters from July through December over the Scotian Shelf, in the Gulf of St. Lawrence, in the Bay of Fundy, and off Newfoundland. The adjusted Canadian quota for 2009 was 553.8 t . t. A total of 429 licensed fishermen participated in the directed bluefin fishery using rod and reel, handlines, electric harpoon and trap nets to harvest 469 t . Each fish harvested is individually tagged with a unique number and it is mandatory to have every fish weighed out at dockside.

The swordfish fishery in Canadian waters takes place from April to December. Canada's adjusted swordfish quota for 2009 was 1343.2 t with landings reaching 1300 t . The tonnage taken by longline was 1051.8 t while 248 t were taken by harpoon. Only 44 of the 77 licensed swordfish longline fishermen landed fish in the 2009 fishery.

The other tunas (albacore, bigeye and yellowfin) are at the northern edge of their range in Canada throughout the year. Canadian catches of these species have traditionally been a minor portion of the overall Canadian catch of large pelagic species. Porbeagle is the only shark species for which there is a directed longline fishery and the combined directed and by-catch harvests were 62 t in 2009.

All commercial vessels fishing pelagic species are required to hail out their intention to fish prior to a trip and hail in any harvests. The Canadian Atlantic statistical systems provide real time monitoring of catch and effort for all fishing trips on pelagic species. At the completion of each fishing trip, independent and certified Dockside Monitors must be present for off-loading, and log record data must be submitted by each fisherman whether fish are harvested or not.

The Annual Report of Canada contains details of recent scientific initiatives, and interested parties are referred to that document. In addition, a population dynamics specialist has been retained on a full time basis, and this individual will be devoted to ICCAT-related work.

## Cape Verde

In 2009, the Cape Verde industrial and semi-industrial tuna fleet was comprised of about 70 operational vessels. The total catch amounted to 10,583 tons ( t ), caught mainly with purse seine and pole and line in the industrial fishery or semi-industrial fishery and with hand line in artisanal fishing. This shows a notable declining trend as compared to the previous year. There are no fishing activities targeting sharks, but due to the fragility of our surveillance, sharks are often part of the by-catches of the foreign longline fleet that fishes in the Cape Verde EEZ. The sport fishery has been the target of a reasonable demand but there is not yet any clear, detailed regulation on this matter. Billfishes are caught in Cape Verde waters, mainly by EU vessels and sport fishing. The licensed foreign fleet, fishing in the Cape Verde EEZ, is based on fishing agreements or contracts. These vessels are mostly from European Union and Asian countries. The objective of the research is to make recommendations for optimal and sustainable exploitation of the aquatic living resources, so as to achieve the economic and social objectives established in the policy on development. Research on fishing and the environment and socio-economic studies are thus of considerable importance for the development of fishing. Cape Verde submits information related to catches, and thus contributes to the updating of statistics and the ICCAT stock assessments.

## China (People's Republic)

Longline is the only fishing gear used by the Chinese fishing fleet to fish tunas in the Atlantic Ocean. Twenty-six (26) Chinese tuna longliners operated in 2009, with a total catch (in round weight) of $6,357.5 \mathrm{t}$ including tuna, tuna-like species and sharks, 938.8 t less than that of $2008(7,296.3 \mathrm{t})$. The target species were bigeye tuna and bluefin tuna, whose catches in 2009 amounted to $4,973 \mathrm{t}$ and 41.7 t , respectively. Bigeye tuna was the major target species in the Chinese catch, accounting for $78.2 \%$ of the total; however, this was 713 t lower than that of 2008 ( $5,686 \mathrm{t}$ ). Yellowfin tuna, swordfish and albacore were taken as by-catch. The catch of yellowfin tuna decreased from 649 t in 2008 to 462 t in 2009. The catch of swordfish was 383 t , with a decrease from the previous year ( 562 t in 2008). The catch of albacore was 116 t , which represented a $136.7 \%$ increase from the previous year.

The data compiled, including Task I and Task II as well as the number of fishing vessels have been routinely reported to the ICCAT Secretariat by the Bureau of Fisheries (BOF), Ministry of Agriculture of the People's Republic of China. The PRC has carried out a national scientific observer program for the tuna fishery in ICCAT
waters since 2001. One observer has been dispatched on board one Chinese Atlantic tuna longline fishing vessel covering the area of $6^{\circ} 13^{\prime} \mathrm{N} \sim 14^{\circ} 15^{\prime} \mathrm{N}, 30^{\circ} 51^{\prime} \mathrm{W} \sim 35^{\circ} 36^{\prime} \mathrm{W}$ since November, 2009. Data of target species and non-target species (sharks, sea turtles, especially) were collected during the observation.

In terms of implementation of the relevant ICCAT conservation and management measures, BOF requires all fishing companies operating in the Atlantic Ocean to report their fisheries data on a monthly basis to the Branch of Distant Water Fisheries of China Fisheries Association and the Tuna Technical Working Group in order to comply with the catch limits. BOF has established a fishing vessel management system, including the issuance of licenses to all the approved Chinese fishing vessels operating on the high seas of world oceans. The Chinese high seas tuna fishing fleet has been required to be equipped with a VMS system since October 1, 2006. BOF has strictly followed the National Observer Program and the ICCAT Regional Observer Program for transshipment at sea.

## Côte d'Ivoire

An international fleet of large tuna vessels lands and/or transships at the port of Abidjan. Thus, in 2009, 52 vessels (10 French, 26 Spanish, 11 Ghanaian and 5 Korean and Guinea cargo vessels) landed and transshipped 133,796 tons ( t ) of major tunas and 23,605 t of "faux poissons" for sale on the local market.

The Centre de Recherches Océanologiques (Center for Oceanographic Research) and equivalent institutions of the flag countries of this international fleet (notably the IRD of France and the IEO of Spain) have implemented a permanent statistical monitoring systemont of their activity.

Moreover, an artisanal driftnet fishery (about 200 canoes), which is more or less active, landed close to $29,000 \mathrm{t}$ of tunas (yellowfin: 649 t ; skipjack: 5,330 t; black skipjack: $3,170 \mathrm{t}$; frigate tuna: 19,684 t) and associated species (billfishes: 205.7 t ; sharks: 72.7 t ). This fishery is monitored jointly by the CRO and the Direction des Productions Halieutiques (Directorate of Fishing Production).

## Croatia

The total Croatian catch of bluefin tuna in 2009 was 618.6 metric tons ( t . Bluefin tuna were predominantly transferred into farming cages ( $608.96 \mathrm{~kg}, 98.44 \%$ ), and $9.65 \mathrm{t}(1.56 \%)$ were landed. Catches of bluefin tuna were mostly made by purse seiners $(98.51 \%)$, while the remainder was caught using hook and line gears.

The total Croatian catch of Mediterranean (Adriatic) swordfish amounted to $3,119 \mathrm{~kg}$ in 2009.
Significant improvements in fleet registry and data collection were made in 2009, enabling Croatia to report more detailed data on bluefin tuna and other tuna-like species. Research was continued on the growth and reproductive biology of bluefin tuna. A national sampling program targeting bluefin tuna harvested from aquaculture facilities has been carried out. Further activities to increase MSC activities (including VMS and electronic logbooks) have been undertaken.

Preliminary results from the 2010 bluefin tuna fishing season and small pelagic fishing are indicating a higher abundance of both juvenile and adult bluefin tuna in the Adriatic Sea than in the previous years.

Croatia has adopted the Regulation on the catch, farming and trade of bluefin tuna that includes provisions of ICCAT Recommendations 06-07, 08-12, 08-05, 09-06 and 09-11 and transposes these into national legislation in full. Croatia implemented the Regional Observers Programme (ROP) on bluefin tuna farms in 2009, in full accordance with the provisions of ICCAT Recommendation 08-05.

Croatia has undergone significant changes in terms of organization of its inspection services.

## European Union

In recent years, the EU fleets have caught close to $40 \%$ of the total ICCAT catches which amounted to 174,000 tons in 2009. These 2009 catches are increasing slightly compared to the 160,000 tons in 2008 , but they continue to be less than the catches of close to $300,000 \mathrm{t}$ that were observed for the EU countries in the early 1990s. Eight EU countries carry out tuna fishing in the Atlantic and Mediterranean, in descending order of the catches in 2009: Spain $(112,000 t)$, France ( $32,000 t$ ), Italy ( $13,600 t$ ), Portugal ( $10,700 \mathrm{t}$ ), Greece ( $2,700 \mathrm{t}$ ), Ireland $(2,100$ $\mathrm{t})$, Malta and Cyprus. The major species caught by the EU countries in 2009 were yellowfin tuna ( $51,400 \mathrm{t}$ ) and
skipjack tuna ( $45,400 \mathrm{t}$.), swordfish and bigeye tuna ( $20,000 \mathrm{t}$ each) ), albacore ( $17,500 \mathrm{t}$ ), and bluefin tuna ( $11,000 \mathrm{t}$ ). It is noted that the 2009 catches of tropical tunas have been, as in 2008, increasing slightly, albacore and bluefin tuna catches were have declined again in 2009. All the traditional fishing gears are active in the EU: purse seiners, baitboats, longliners, hand lines, trolling line, driftnets, harpoons, pelagic trawls, traps and sport fishing.

It is noted that in 2010 the financial support from the EU was decisive in launching the large-scale programme on bluefin tuna that was being initiated by ICCAT. The EU also finances to a large extent and routinely since 2001 the collection of biological data and considerable research projects on tunas of all its member countries. Task I and Task II statistical data which were submitted in 2010 to ICCAT by the EU countries are generally complete and in accordance with ICCAT rules. It is further noted that the EU also supports observer programmes on various fleets, tropical purse seiners with about $10 \%$ of the fishing effort monitored by observers and, since $2009,100 \%$ of the fishing days are observed on the purse seiners fishing bluefin tuna in the Mediterranean. Biological sampling of tropical tunas of European purse seiners is also continuing as well as being routinely carried out in the Abidjan canneries. Also of note in 2010 is an effort by France to better estimate the activities and the catches of its artisanal fisheries on FADs for billfishes and tunas Martinique and Guadeloupe.

In addition, the active participation is noted of European scientists at all the ICCAT scientific meetings as well as the large number of SCRS documents in 2010 co-authored by EU scientists on all subject areas of ICCAT research. The EU countries conduct considerable research of a more fundamental nature on tunas, for example, on the ecosystems, the reduction of by-catches, tunas-environment relationships, tuna behavior, FADs, spawning and the production of larvae and juvenile bluefin tuna, etc. Scientists from EU countries actively participate, for example, within the framework of the CLIOTOP/GLOBEC Programme which has broad tuna research objectives that are multi-disciplinary and worldwide, and which are aimed at carrying out better modelling of the sustainable exploitation of the tuna resources based on the environment and the ecosystems.

## Ghana

The tuna industry in Ghana comprises the skipjack (Katsuwonus pelamis), yellowfin (Thunnus albacares) and bigeye tuna (Thunnus obesus). 21 baitboats, 11 purse seiners and 4 Longliners currently fishing within the EEZ of Ghanaian coastal waters and beyond exploit these tuna species amongst other minor tuna-like species such as black skipjack (Euthynnus alletteratus).

During the year under review, skipjack catches were the highest (54.3\%) followed by yellowfin ( $27.6 \%$ ) and bigeye tunas (15.8\%) respectively. Both fleets use Fish Aggregating Devices (FADs) in fishing and collaborate extensively in sharing their catch during fishing operations. Over $80 \%$ of catches are conducted off FADs. Catches for 2009 rose slightly to 66,470 metric tons ( t ) from $64,093 \mathrm{t}$ in 2008, an increase of approximately 2,400 t.

Recent improvements in sampling, coupled with the provision of more logbook information from the fishery, have contributed to a better understanding of the time-area distribution of the species. It is envisaged that further synthesis of the database on Ghana since 1980-2009 would give a clear picture on the catch and species composition of the entire catch in relation to the collaborative fishing strategies and innovations and other factors influencing catchability of the species.

Ghana's Action Plan to strengthen the collection of statistical data and control measures to ensure the implementation of conservation and management measures were presented to the commission.

An observer programme was organized in March-May 2009 on board four purse seine vessels with the aim of training officers on the proper methods of estimating catches and filling out of information in logbooks. Also noted was massive use of FADs throughout the programme. In one recommendation, among others, it was suggested that due to the massive use of FADs and its attendant effect on juvenile destruction, a precautionary approach should be made to safeguard the industry.

Beach sampling of billfishes continued off the western coast of Ghana from artisanal drift gill operators. Revision of Task 3 for the period 1996-2009 has been finalized and standardized CPUE series will be carried out in 2011.

## Japan

Longline is the only tuna-fishing gear deployed by Japan at present in the Atlantic Ocean. The final coverage of logbooks from the Japanese longline fleet was $90-95 \%$ before 2008. The current coverage for 2009 is estimated to be about $90 \%$. In 2009, the number of fishing days was about 25,000 days, which was close to the average value in the recent ten year period. The catch of tunas and tuna-like fishes (excluding sharks) is estimated to be about $30,000 \mathrm{t}$, which is about $90 \%$ of the past ten years' average catch. The most important species was bigeye tuna, representing $55 \%$ of the total tuna and tuna-like fish catch in 2009. The next dominant species was yellowfin tuna, which represented $19 \%$ in weight, and the third species was bluefin tuna ( $7 \%$ ). Observer trips on longline boats in the Atlantic were conducted and a total of about 530 fishing days were monitored. In addition to the logbook submission mentioned above, the Fisheries Agency of Japan (FAJ) has set catch quotas for western and eastern Atlantic bluefin as well as for northern and southern Atlantic swordfish, blue marlin, white marlin and bigeye tuna, and has required all tuna vessels operating in the Atlantic Ocean to submit catch information every day (bluefin tuna) and every ten-day period (for other tunas) by radio or facsimile. All Japanese longline vessels operating in the Convention area have been equipped with satellite tracking devices (VMS) onboard. In accordance with ICCAT recommendations, the FAJ has taken the necessary measures to comply with its minimum size regulations, time area closures, etc. by Ministerial Order. Each species statistical or catch document programs has been conducted. Records of fishing vessels larger than 24 meters in length overall (LSTLVs) have been established. The FAJ has dispatched patrol vessels to the North Atlantic to monitor and inspect Japanese tuna vessels and also to observe the fishing activities of other nations' fishing vessels, and has inspected landings at Japanese ports to enforce the catch quotas and minimum size limits. Prior permission from the FAJ is required in the case that Japanese tuna longline vessels tranship tuna or tuna products to reefers at foreign ports or at sea.

## Korea

In recent years, the annual catch of tuna and tuna-like species by Korean tuna longliners and purse seiners in ICCAT areas has increased and ranges from 2,438 to $4,668 \mathrm{t}$, with an average of 3,773 from 2005 to 2009. The major species were bigeye tuna ( $55.6 \%$ of total), yellowfin tuna ( $16.5 \%$ ) and bluefin tuna ( $10.5 \%$ ) during the recent five years, of which bigeye tuna and yellowfin tuna were the most important species in terms of catch size and high commercial value in sashimi markets. In 2009, 24 Korean longliners and one purse seiner operated in the ICCAT area and caught a total of $3,856 \mathrm{t}$, which was a decrease as compared to the catch of the previous year. Almost $78 \%$ of the total catch was comprised of the three major species, of which the bigeye tuna catch was $2,134 \mathrm{t}(55 \%$ of total), albacore $458 \mathrm{t}(12 \%)$ and yellowfin tuna $433 \mathrm{t}(11 \%)$. It was apparent that the yellowfin tuna catch sharply decreased from 993 t in 2008 to 433 t in 2009, while albacore catch increased from 147 t in 2008 to 458 t in 2009. Korean longliners operated mainly in the tropical area of the Atlantic Ocean and targeted bigeye tuna and yellowfin tuna. The fishing season was throughout the year, from January to December in 2009, in the central Atlantic Ocean $\left(15^{\circ} \mathrm{N} \sim 5^{\circ} \mathrm{S}, 0^{\circ} \mathrm{W} \sim 40^{\circ} \mathrm{W}\right)$. One Korean purse seiner based in Malta fished bluefin tuna in the Maltese area $\left(34^{\circ} \sim 35^{\circ} \mathrm{N}, 13 \sim 15^{\circ} \mathrm{E}\right)$ of the Mediterranean Sea for one month. During the 2009 fishing season, a total of 102 t of bluefin tuna was caught in a joint fishing operation (Korea and France). The Korean catch of bluefin tuna accounted for $77 \%$ of the Korean quota ( 132.26 t ) for 2009. The CPUE ( $\mathrm{t} / \mathrm{set}$ ) of the bluefin tuna catch by joint fishing fleets was 42 t /set.

## Morocco

The fishing of tuna and tuna-like species reached a production of 13,956 tons in 2009, the same level of general catches as in 2008.

The major species caught along the Moroccan coasts are bluefin tuna, swordfish, bigeye tuna, yellowfin tuna, albacore, small tunas, and some shark species.

The collection of statistical data and effort data is carried out in an exhaustive manner by the fisheries administration structures, such as the Département des Pêches (Department of Fishing) and the Office National des Pêches (National Office of Fishing), which are located throughout the Atlantic and Mediterranean coasts of Morocco. Monitoring of the export of fishing products is also carried out by the Office des Changes (the Exchange Office).

As regards scientific work, the Institut National de Recherche Halieutique-INRH (National Institute of Fisheries Research), through its Regional Centers (of which there are five) covering the entire Moroccan coast, reinforces the collection of biological data on the major species (bluefin tuna and swordfish). The Regional Center of the

INRH in Tangiers serves as coordinator of the collection of all these data. In recent years, the monitoring of other species has been started, particularly tropical tunas (bigeye tuna among others), with extensive research work in areas located to the south of Morocco.

Considerable progress has also been reported as regards the collection of biological data, as noted by the series of scientific documents as well as the Task II databases submitted by Moroccan scientists at the various SCRS meetings for the stock assessments on tunas.

## Mexico

High seas longline fishing is directed at yellowfin tuna (Thunnus albacares), in which other species groups are caught, and is concentrated in oceanic waters and limited to the Exclusive Economic Zone (EEZ) in the Gulf of Mexico and Caribbean Sea. Of the 37 large vessels with fishing permits, currently 29 operate that have carrying capacity. Among the coastal states of the Gulf of Mexico and Caribbean Sea, Veracruz and Yucatan contribute $85 \%$ of the total catch. The major catch of yellowfin tuna is obtained during the summer months. The product is mainly exported fresh to the United States. The catch of yellowfin tuna reported a historical maximum of $1,390 \mathrm{t}$ in 2000, while in 2003 there was a reported gradual decrease from $1,362 t$ to $890 t$ in 2007, followed by a slight increase of 956 t in 2008 and $1,210 \mathrm{t}$ in 2009. With regard to fishing effort, a marked decrease in fishing effort was noted in 2009. The total report catch in 2009 (catch stored in holds, released live and dead discards) was $1,723 \mathrm{t}$, comprised of yellowfin tuna ( $73 \%$ ), and incidental by-catch ( $27 \%$ ).

In 2009, efforts in Mexico were directed at improving the quality and quantity of scientific information, through validation, publication and interrelating. Additionally, the training and updating of observers on board vessel in the Gulf of Mexico was also carried out. The purpose was the timely compliance with national as well as international commitments within the framework of management of the longline fishery. Further, priority was given to the scientific dissemination of these achievements through technical meetings, fora, and educational exchanges that have involved participation from the industrial, governmental and educational sectors

## Norway

In light of the critical stock situation for Atlantic bluefin tuna, Norway has adopted a prohibition for Norwegian vessels to fish and land bluefin tuna in Norway's territorial waters, in the Norwegian Economic Zone and in international waters. It is also prohibited to import and export Atlantic bluefin tuna, bigeye tuna and Atlantic swordfish in Norway without valid catch documentation.

No catches of Atlantic bluefin tuna were reported by Norway in 2009. Only one visual sighting of a juvenile bluefin tuna was reported in western Norway in June 2009.

Norway continuously works on historical data, and aims to put the data on this species into an ecosystem perspective. Extensive data and preliminary results on catch per unit effort (CPUE) from the Norwegian bluefin tuna fleet for the period 1950-1980 was made available for SCRS in 2009.

Norway participated in all major international scientific meetings concerning Atlantic bluefin tuna in 2009.

## Russia

The Fishery. In 2009 a specialized purse-seine tuna fishery was carried out periodically in the Equatorial area by two purse seiners in an experimental mode of operation. The total catch amounted to 336 t ( 33 t of yellowfin tuna, 43 t of bigeye tuna and 260 t of oceanic skipjack).

The trawl fishery vessels caught 161 t of tunas and 366 t of bonito as by-catch from the Central-East Atlantic Ocean during 2009. In the first half of 2010, the trawl fishery vessels caught 168 t of tunas and 426 t of bonito.

Scientific research and statistics. In 2009 and the first half of 2010, the observers collected material onboard trawlers. The tuna species, size composition and proportions of all fish species in the total catches were estimated.

A comparative morphologic analysis of the teeth and body parameters of blue shark from the Atlantic and eastern Pacific Oceans was carried out.

The comparison indicates that the teeth morphology of Atlantic and Pacific sharks is similar. Sharks from different oceans differed in body proportions. Sexual dimorphism was found in blue sharks.

Implementation of ICCAT conservation and management measures. During the fishery in the areas where tunas and tuna-like species occur in catches, the ICCAT requirements and recommendations concerning restrictions on the tuna fishery, and a ban imposed on fishing species under quotas were observed.

## Senegal

In Senegal, tuna and tuna-like species are mostly caught by the industrial fishery comprised of baitboats targeting the major tuna species: yellowfin tuna (Thunnus albacares), bigeye tuna (Thunnus obesus) and skipjack tuna (Katsuwonus pelamis), and longliners searching for swordfish (Xiphias gladius). Furthermore, a part of the artisanal fisheries uses hand line, pole and line and purse seine to catch small tunas: black skipjack (Euthynnus alletteratus), mackerel (Scomberomus tritor), plain bonito (Orcynopsis unicolor) and Atlantic bonito (Sarda sarda), wahoo (Acanthoncybium solandri), and frigate tuna (Auxis thazard). Billfishes (swordfishXiphias gladius, blue marlin -Makaira nigricans and sailfish-Istiophorus platypterus are also caught. The sport fishery targets billfishes (marlins and sailfish) during the fishing season that goes from May to December.

In 2009, the seven Senegalese purse seiners landed 6,720 tons $(t)$, comprised of $1,157 \mathrm{t}$ yellowfin tuna, $4,513 \mathrm{t}$ skipjack tuna, $1,041 \mathrm{t}$ bigeye tuna, 6 t black skipjack and 4 t frigate tuna. The longline fishery, which is comprised of four vessels, landed 590 t . The catches were made up of 195 t of swordfish, 327 t of sharks, 11 t of yellowfin tuna, 24 t of blue marlin, 2 t of sailfish and 27 t of fins.

With regard to the artisanal fisheries, the landings of all species mixed was estimated at 5,315 t in 2009. The sport fishery catches amounted to 78 t of sailfish and 37 t of marlins for an effort of 638 trips.

As regards scientific work, the collection of statistical data on the tunas landed by the national and foreign fleets (mainly French and Spanish) based at Dakar is carried out regularly by the team at the Centre de Recherches Océanographiques de Dakar/Thiaroye (CRODT). The information obtained is supplemented by the catches made from various sources (boat owners, Direction des Pêches Maritimes, etc.).

Sampling is conducted during the landings of the national and foreign vessels at the port of Dakar by a team of three. In 2009, 226 multi-species size samples were taken from Senegalese baitboats. Samñling of billfishes (mostly sailfish-Istiophorus platypterus) is also carried out at the major landing sites of the artisanal fishery, mainly at Soumbédioune, Yoff and Mbour.

The ICCAT conservation and management measures are well monitor by Senegal. The system of monitoring, control and surveillance of all the fishing activities in place at port permits carrying out inspections as well as identifying any vessel involved in illegal fishing activities.

## Turkey

During the course of 2009, the total catch of tuna and tuna-like fishes amounted to $8,633 \mathrm{t}$. In 2009, Turkey's total catches of bluefin tuna, albacore, Atlantic bonito and swordfish were $665,4 \mathrm{t}, 631 \mathrm{t}, 7,036 \mathrm{t}$, and 301 t , respectively. All bluefin catch was caught by purse seiners, the majority of which have an overall length of 3050 m and a GRT of 200-300. The fishing operation was conducted intensively off Antalya Bay and in the region between Antalya Gazi Paşa and Cyprus. In the Mediterranean, fisheries were conducted in the region between Cyprus-Turkey and in the Cyprus-Syria region. The highest bluefin tuna catch was obtained in June. Recommendations and resolutions imposed by ICCAT were transposed into national legislation and implemented. All the conservation and management measures regarding bluefin tuna fisheries and farming are regulated by national legislation through notifications, considering ICCAT's related regulations. The Fisheries Information System has been updated in order to meet the requirements of data exchange at the national and regional level. Major research activities in 2009 focused on albacore.

## United States

The total (preliminary) reported U.S. catch of tuna and swordfish, including dead discards, in 2009 was 9,605 metric tons ( t ), an increase of about $16 \%$ from $8,304 \mathrm{t}$ in 2008. Estimated swordfish catch (including estimated dead discards) increased from 2,530 t in 2008 to $2,838 \mathrm{t}$ in 2009, and provisional landings from the U.S. fishery for yellowfin slightly increased in 2009 to $2,802 \mathrm{t}$ from 2,407 t in 2008. In 2009, U.S. vessels fishing in the
northwest Atlantic caught an estimated $1,228 \mathrm{t}$ of bluefin, an increase of 307 t compared to 2008. Provisional skipjack landings increased by 52 t to 119 t from 2008 to 2009, estimated bigeye landings slightly increased by about 28 t compared to 2008 to an estimated 516 t in 2009, and estimated albacore landings decreased from 2008 to 2009 by 60 t to 188 t .

In 2009, the United States continued research to enhance the knowledge of tuna and tuna-like species in areas such as age and growth, stock structure, biological characteristics, migration patterns, habitat utilization, etc. As in previous years, the United States maintained its scientific observer coverage of the pelagic and bottom longline fleets and the gillnet fisheries. A description of time-area closures and the impact of such management measures to reduce the dead discards in the swordfish pelagic longline fisheries are also provided.

## Uruguay

In 2009, nine vessels operated using surface longline and five vessels used deep longline. The latter vessels fished jointly with a Japanese company within a bigeye tuna prospection project. The total catch (preliminary) landed and reported in 2009 was approximately 2,525 tons ( t ).

## Research and statistics

Various activities were carried out in 2009 related to statistics, research and management. Some of these activities were developed jointly with other national and international institutions. In 2009 fisheries-independent research was initiated on board DINARA's scientific research vessel. The overall objective was to collect more detailed information on the species in the oceanic pelagic environment and to carry out experiments on mitigating measures, etc.

## Research

Research was developed mainly information from the fishing sector and from the Observers Program (PNOFA) and during 2009 data obtained on the research vessel were integrated. PNOFA covered an important part of the activity of the national flag fleet and $100 \%$ of the deep longline fleet that participated in the bigeye prospection research. In 2009, there were approximately 1,600,000 hooks observed. The tagging program continued in 2009, with 473 fish tagged with tags provided by ICCAT ( 5 recoveries), as did diffusion and circulation activities.

Uruguay collaborated in various inter-sessional meetings (swordfish, porbeagle), submitting papers for the assessments and the data preparatory meetings. Genetic studies are being carried out jointly with other countries for species identification and age and growth studies on Tetrapturus pfluegeri. Work was done for the preparation of the ICCAT shark identification sheets and information on sharks was updated (Chapter 2, Section 2.2.1) of the new ICCAT Manual. Research has been carried out on the monitoring and evaluation of the problem of the incidental catch of sea birds, as well as the implementation of mitigation measures for their enforcement on the fleet.

Studies have also been carried out on feeding, migration, habitat use, genetics, among others, of marine turtles. Experiments continue to be conducted with circle hooks in the longline fleet that uses American type longline as well as well on the DINARA research vessel. Research continued on marine mammals that interaction with the fleet. In 2009 a prospection project was carried out to determine the possibility of fishing bigeye tuna (T. obesus) in Uruguayan waters. For this, five Japanese vessels of approximately 50 m in length operated between March and September within the 200 mile area of Uruguay, mainly on the continental shelf. During this prospection, 501 sets were made, with $100 \%$ coverage by Uruguayan observers. Besides, these vessels continued testing mitigation measures, using "scarecrow" lines designed by Uruguay.

## Implementation of the ICCAT conservation and management measures

Also continued were the implementation of the "National Action Plan to Reduce the Incidental Catch of Sea Birds in Uruguayan Fisheries" and the "National Action Plan for the Conservation of Chondrichthyes in Uruguayan Fisheries"

Among the national management measures, those referring to minimum size of the catch of swordfish ( 25 kg , $15 \%$ tolerance), bigeye tuna and yellowfin tuna ( 3.2 kg ) remained in effect.

## Venezuela

The Venezuelan fleeet targeting pelagic resources was comprised of 60 industrial vessels in 2009: 46 longliners, 6 purse seiners and 8 baitboats. Besides there were 35 artisanal vessels registered that fish using driftnets and 48 using surface longline. Landings in this year of tunas and tuna-like species from the Atlantic Ocean amounted to $7,103 \mathrm{t}$. Of this amount, $91.6 \%$ were tunas, of which the most important species was yellowfin tuna ( $T$. albacares) with $45 \%$, while catches of skipjack tuna (K. pelamis) and blackfin tuna (T. atlanticus) and bigeye tuna ( $T$. obesus) reached $32 \%, 4 \%$ and $6 \%$, respectively. The incidental catch was comprised of billfishes, parituclarly sailfish (Istiophorus albicans) with $2.2 \%$ and blue marlin (Makaira nigricans) with $1.5 \%$, and sharks whose landings represented $2.3 \% .52 \%$ of the landings were from the purse seine fishery, $19 \%$ from baitboat, $24 \%$ from longline, and $5 \%$ from the artisanal fisheries. In 2009, research continued on the fishery for large pelagics, including tunas, billfishes and sharks. The scientific observer program on board industrial longline vessels continued as did coverage of the sport fishing tournaments.

## - Cooperating Parties, Entities or Fishing Entities

## Chinese Taipei

In 2009, the total number of authorized longline vessels in the Atlantic Ocean was 109, which included 60 longliners authorized to target bigeye tuna and 49 to target albacore. The catch of the longline fleet declined from 45,437 metric tons ( t ) in 1998 to $28,090 \mathrm{t}$ in 2009, and the catches of bigeye tuna, yellowfin tuna and albacore were $13,252 \mathrm{t}, 1,391 \mathrm{t}$ and $9,541 \mathrm{t}$, respectively. Bigeye and yellowfin tuna catches increased from those of 2008, which was mainly due to the increase in fishing effort from the low fishing effort level because of the high fuel price in 2008. However, albacore catches decreased for some longliners that were temporarily out of operation. There were 25 observers placed on fishing vessels in the Atlantic Ocean, and the observer coverage rate was above the requirement set by ICCAT. The research projects conducted by scientists in 2009 included CPUE standardizations for North and South Atlantic albacore, swordfish and bigeye tuna, and distribution of ecologically related species in the Atlantic Ocean. Scientific documents on these research projects were submitted to various inter-sessional scientific meetings organized by ICCAT.

## 8. Executive Summaries on species

The Committee reiterates that, in order to obtain a more rigorous scientific understanding of these Executive Summaries, readers consult previous Executive Summaries as well as the corresponding Detailed Reports, which are published in the Collective Volume series.

The Committee also notes that the texts and tables in these summaries generally reflect the information that was available to ICCAT immediately before the plenary sessions of the SCRS, as they were drafted by the Species Group meetings. Therefore, catches reported to ICCAT during or after the SCRS meeting may not be included in the Summaries.

### 8.1 YFT - YELLOWFIN TUNA

A stock assessment for yellowfin tuna was conducted in 2008, at which time catch and effort data through 2006 were available. The catch table presented in this Executive Summary (YFT-Table 1) has been updated to include catches through 2009. Readers interested in a more complete summary of the state of knowledge on yellowfin tuna should consult the detailed report of the 2008 ICCAT Joint Stock Assessment of Atlantic Skipjack and Yellowfin Tuna (SCRS/2008/016).

Other information relevant to yellowfin tuna is presented elsewhere in this SCRS Report:

- The Tropical Tunas Work Plan (Appendix 5) includes plans to address research and assessment needs for yellowfin tuna.

## YFT-1. Biology

Yellowfin tuna is a cosmopolitan species distributed mainly in the tropical and subtropical oceanic waters of the three oceans. The sizes exploited range from 30 cm to 170 cm FL; maturity occurs at about 100 cm FL. Smaller fish (juveniles) form mixed schools with skipjack and juvenile bigeye, and are mainly limited to surface waters, while larger fish form schools in surface and sub-surface waters. The main spawning ground is the equatorial zone of the Gulf of Guinea, with spawning primarily occurring from January to April. Juveniles are generally found in coastal waters off Africa. In addition, spawning occurs in the Gulf of Mexico, in the southeastern Caribbean Sea, and off Cape Verde, although the relative importance of these spawning grounds is unknown. Although such separate spawning areas might imply separate stocks or substantial heterogeneity in the distribution of yellowfin tuna, a single stock for the entire Atlantic is assumed as a working hypothesis, taking into account the transatlantic migration (from west to east) indicated by tagging, a 40-year time series of longline catch data that indicates yellowfin are distributed continuously throughout the entire tropical Atlantic Ocean, and other information (e.g., time-area size frequency distributions and locations of fishing grounds). Movement rates, routes, and local residence times remain highly uncertain, however. Males are predominant in the catches of larger sized fish, which may indicate that there are important differences between sexes with respect to growth and/or natural mortality. Natural mortality is assumed to be higher for juveniles than for adults; this is supported by tagging studies for Pacific yellowfin. Uncertainties remain as to the scale of these natural mortality rates, however, with important implications for stock assessment.

Growth rates have been described as relatively slow initially, increasing at the time the fish leave the nursery grounds, and is supported by results from tagging data in other oceans. Nevertheless, questions remain concerning the most appropriate growth model for Atlantic yellowfin tuna. A recent study (Shuford et al. 2007) developed a new growth curve using daily growth increment counts from otoliths. The results of this study, as well as other recent hard part analyses, do not support the concept of the two-stanza growth model (initial slow growth) which is currently used for ICCAT (as well as other management bodies) yellowfin tuna stock assessments and was developed from length frequency and tagging data. This discrepancy in growth models could have implications for stock assessments; however, recent analyses indicate that assuming this alternative growth model would result in only moderate changes to estimates of stock status using current age-structured assessment models and assumptions of natural mortality vectors.

The younger age classes of yellowfin tuna exhibit a strong association with FADs (fish aggregating devices/floating objects, which can be natural or artificial). The Committee noted that this association with FADs, which increases the vulnerability of these smaller fish to surface fishing gears, may also have a negative impact on the biology and on the ecology of yellowfin due to changes in feeding and migratory behaviors.

## YFT-2. Fishery indicators

In contrast to the increasing catches of yellowfin tuna in other oceans worldwide, there has been a reduction in overall Atlantic catches, with an overall decline of $39 \%$ from the peak catches of 1990, although catches have increased by $10 \%$ (to a provisional $118,871 \mathrm{t}$ ) relative to 2006 , the last year of data available for the assessment). Recent trends have differed between the western and eastern Atlantic, with the overall catches in the west declining by $26 \%$ since 2006. In the eastern Atlantic, on the other hand, catches increased by $23 \%$ since 2006, mainly due to substantial increases in purse seine effort.

In the eastern Atlantic, where overall catches peaked in 1990, purse seine catches declined from $128,729 \mathrm{t}$ in 1990 to less than half that ( $58,319 \mathrm{t}$ ) in 2006, but then increased by nearly a third from that level to $76,392 \mathrm{t}$ in 2009 (YFT-Table 1; YFT-Figure 2). Baitboat catches declined by half from 1990 to 2006(from 19,648 t to $10,434 \mathrm{t}$ ), but have increased by $5 \%$ to 10,949 in 2009 . Longline catches, which were $10,253 \mathrm{t}$ in 1990 , have fluctuated since between $5,790 \mathrm{t}$ and $14,638 \mathrm{t}$ and were $7,219 \mathrm{t}$ in 2006 (a $30 \%$ decrease from 1990), increasing again by $8 \%$ between 2006 and 2009 to 7808 t. In the western Atlantic where overall catches peaked in 1994, purse seine catches declined by three-quarters from 1994 to 2006 (from 19,612 t to $4,442 \mathrm{t}$ ), and by 2009 had decreased by another two-thirds relative to 2006 ( $1,365 \mathrm{t}$ ). Baitboat catches declined by nearly two-thirds between 1994 and 2006, from 7,094 t to 2,695 t, and in 2009 were reduced by half again from the 2006 level (to 1331 t ). Longline catches, which were $11,343 \mathrm{t}$ in 1994, have fluctuated since between $10,059 \mathrm{t}$ and $16,019 \mathrm{t}$, were $14,249 \mathrm{t}$ in 2006 (a $26 \%$ increase from 1990) and remained about the same by 2009 ( $14,992 \mathrm{t}$ ). It was noted that Brazilian catches declined in 2008-2009 as a result of reductions in effort and targeting; this may also be the case for Venezuela in 2007-2009. However, United States catches during 2008-2009 declined substantially despite maintaining similar effort levels to previous years. The most recent available catch distribution is given
in YFT-Figure 1. However, it should be noted that official reports are not yet available from several Contracting and/or non-Contracting Parties, and some of these figures are based upon data provided by CPC scientists and/or derived from recent catch levels.

The nominal effort in the purse seine fishery had been declining through 2006. As an indicator, the number of purse seiners from the European and associated fleet operating in the Atlantic had declined from 44 vessels in 2001 to 25 vessels in 2006 (the last year of data included during the assessment), with an average age of about 25 years (see SKJ-Figure 3 for trends in number of vessels and carrying capacity). Since then, however, the number of purse seiners has increased by $50 \%$ to 37 , as vessels have moved from the Indian Ocean to the Atlantic. At the same time, the efficiencies of these fleets have been increasing, particularly as the vessels which had been operating in the Indian Ocean tend to be newer and with greater fishing power and carrying capacities. On the other hand, since 2006 the European and associated baitboat fleet, based in Dakar, varied in number only slightly.

Several scientific documents were presented which were descriptive of the catches by country fleets. Catch rate trends for a number of fisheries were considered during the assessment, Examination of nominal catch rate trends from purse seine data suggest that catch-per-unit effort was stable or increasing in the East Atlantic (the catch rate trends of individual country fleets differ somewhat), and was clearly declining in the West Atlantic (YFT-Figure 3). If effort efficiency is estimated to have continued to increase as has been assumed in the past, adjustments for such efficiency change would be expected to result in a steeper declining trend. However, the decrease in western Atlantic purse seine catch rates could be linked to specific environmental conditions (e.g. high surface temperatures, reduced availability of prey, etc.), especially considering that decreases are also seen in skipjack catch rates, and it is therefore difficult to conclude that these rates reflect abundance trends. Baitboat catch rate trends (YFT-Figure 4) exhibit large fluctuations, with a somewhat declining overall trend. Such large fluctuations reflect changes in local availability, which (although of great import to the respective fisheries) do not necessarily reflect stock abundance trends (i.e. localized environmental changes as well as changes in migratory patterns may produce such results). Standardized catch rates for the longline fisheries (YFT-Figure 5) generally show a declining trend until the mid-1990s, and have fluctuated without clear trend since.

The average weight trends by fleet (1970-2006) are shown in YFT-Figure 6. The recent average weight in European purse seine catches, which represent the majority of the landings, has declined to less than half of the average weight of 1990 . This decline is at least in part due to changes in selectivity associated with fishing on floating objects, although there have been recent indications that the mean weight of large fish caught in free schools has been declining. A declining trend is also reflected in the average weight of eastern tropical baitboat catches. Longline mean weights have also followed a generally declining trend, although estimates have been highly variable in recent years.

Apparent changes in selectivity can also be seen in the overall trends in catch at age shown in YFT-Figure 7. The variability in overall catch at age is primarily due to variability in catches of ages 0 and 1 (note that the catches in numbers of ages 0 and especially 1 were particularly high during the period 1999-2001). These ages are generally taken by the surface fisheries around FADs.

## YFT-3. State of the stock

A full stock assessment was conducted for yellowfin tuna in 2008, applying both an age-structured model and a non-equilibrium production model to the available catch data through 2006.

An age-structured virtual population analysis (VPA) was conducted using fifteen indices of abundance. The VPA, using results from the base case runs, estimates that the levels of fishing mortality and spawning biomass in recent years have been very close to MSY levels. The estimate of MSY derived from these analyses was $130,600 \mathrm{t}$. This estimate may be below what was achieved in past decades because overall selectivity has shifted to smaller fish (YFT-Figure 7); the impact of this change in selectivity on estimates of MSY is clearly seen in the results from VPA (YFT-Figure 8). The estimate of relative fishing mortality ( $\mathrm{F}_{2000} / \mathrm{F}_{\text {MSY }}$ ) was 0.84 , and for relative biomass $\left(\mathrm{B}_{2006} / \mathrm{B}_{\mathrm{MSY}}\right)$ was 1.09 .

The stock was also assessed with a production model (ASPIC). Analyses were conducted using either nine separate indices or using a combined index created from all available abundance indices by fleet and gear, and weighting each index by the area covered by that fishery. The estimate of MSY derived using the basic case runs of ASPIC was $146,600 \mathrm{t}$. Although the estimate of MSY was somewhat higher than that from the age structured model, the stock status results are slightly more pessimistic. The estimate of relative fishing mortality ( $\mathrm{F}_{20006} / \mathrm{F}_{\text {MSY }}$ ) was 0.89 , and for relative biomass ( $\mathrm{B}_{2006} / \mathrm{B}_{\text {MSY }}$ ) was 0.83 .

Trajectories of $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ from both age structured (VPA) and the production model (ASPIC) analyses are shown in YFT-Figure 9. When considering the results of each model, it should be noted that each has relative strengths and weaknesses; the production model utilizes all the years of available data but assumes that selectivity across lengths (ages) doesn't change over time, whereas the age structure model can track changes in selectivity but relies on accurate assignment of ages and is restricted to years for which adequate catch at size data are available. The trend estimated from VPA indicates that overfishing ( $\mathrm{F}>\mathrm{F}_{\mathrm{MSY}}$ ) has occurred in recent years, but that the current status is neither overfished ( $B<B_{\text {MSY }}$ ) nor is there over fishing. The more pessimistic ASPIC estimates indicate that there has been both overfishing and an overfished status in recent years, but that overfishing was not occurring in 2006. Bootstrapped estimates of the current status of yellowfin tuna based on each model, which reflect the variability of the point estimates given assumptions about uncertainty in the inputs, are shown in YFT-Figure 10. Examination of the distribution of these estimates from both models shows that about $40 \%$ indicate a sustainable situation, in which the stock is not overfished and overfishing is not occurring (YFT-Figure 11).

In summary, 2006 catches are estimated to be well below MSY levels, stock biomass is estimated to be near the Convention Objective and recent fishing mortality rates somewhat below $\mathrm{F}_{\text {MSY }}$. The recent trends through 2006 indicate declining effective effort and some recovery of stock levels. However, when the uncertainty around the point estimates from both models is taken into account, there was still about a $60 \%$ chance that stock status was not consistent with Convention objectives.

## YFT-4. Outlook

Projections were made considering a number of constant catch scenarios (see YFT-Figure 12 for the results from the age-structured model). These indicate that catches of $130,000 \mathrm{t}$ or less are sustainable during the projection interval, while catches in excess of $130,000 \mathrm{t}$ can lead to overfishing. Maintaining current catch levels $(110,000 t)$ is expected to lead to a biomass somewhat above $B_{\text {MSY }}$.

In terms of equilibrium conditions, the various assessment model results show that increasing fishing mortality in the long term by up to $10 \%$ (depending on the model) to reach $\mathrm{F}_{\text {MSY }}$ would only result in equilibrium yield gains of $1 \%$ to $4 \%$ (YFT-Figure 13) over the expected yields at current fishing mortality levels.

It is noted that catch levels until 2007 had been held in check, despite increasing efficiencies of individual vessels, by a continued decline in the number of purse seine vessels in the eastern Atlantic. This trend has since reversed, and given a continuation of the recent movement of additional, newer vessels from the Indian Ocean into the Atlantic, with a corresponding increase in fishing mortality, the situation should be monitored closely to avoid adverse impacts on stock status.

Yearly catches of small (less than 3.2 kg ) yellowfin tuna in numbers have ranged around $60-75 \%$ of purse seine catches and about $40-80 \%$ of baitboat catches since 2000 , occurring primarily in the equatorial fisheries. The generally declining trends in average weight may still be a cause for concern. Minimum size limits for yellowfin tuna have been shown to be ineffective by themselves, due to difficulties related to the multi-species nature of the fishery. Yield-per-recruit analyses, the results of which are strongly dependent upon the natural mortality vector assumed, have indicated that reductions in fishing mortality on fish less than 3.2 kg could result in gains in yield-per-recruit and modest gains in spawning biomass-per-recruit. The protection of juvenile tunas may
therefore be important and alternative approaches to minimum size regulations to accomplish this should be studied. Evaluations have been conducted on the relative impact of effective effort restrictions on individual fisheries in terms of yield per recruit and spawning biomass per recruit and are presented in the Report of the 2009 Inter-sessional Meeting of the Tropical Tuna Species Group (SCRS/2009/011). This year, a scientific document (SCRS/2010/152) has been presented describing initiatives to develop and test bycatch (including juvenile tuna) mitigation options for tropical purse seine fisheries, with investigations to be conducted in all oceans.

## YFT-5. Effects of current regulations

Recommendation 04-01 implemented a small closure for the surface fishing in the area $0^{\circ}-5^{\circ} \mathrm{N}, 10^{\circ} \mathrm{W}-20^{\circ} \mathrm{W}$ during November in the Gulf of Guinea. Although this regulation is intended to reduce small bigeye catches, the Committee recognizes that its implementation and the change from the previous moratorium to the current regulation will potentially impact yellowfin catches. Given the relatively small time-area coverage of the closure, any reduction in juvenile mortality is expected to be minimal. This expectation is supported by analyses of purse seine catches which were presented to the Committee, confirming that the new closure has been less effective than previous moratoria in reducing the proportional catch of small fish harvest and avoiding growth overfishing, at least with respect to the catches of European and associated fleets. If management objectives include reductions in juvenile mortality, there is a general agreement that larger time/area moratoria are likely to be more precautionary than a smaller moratoria, providing that the moratoria are fully complied with. As requested by the Commission, in 2009 the Committee analysed the closure contained in [Rec. 08-01] and alternative closures. The response to the Commission's request is provided in a separate section of the 2009 SCRS report.

In 1993, the Commission recommended "that there be no increase in the level of effective fishing effort exerted on Atlantic yellowfin tuna, over the level observed in 1992". As measured by fishing mortality estimates from VPA, during the 2008 assessment, effective effort in 2006 appeared to be well below (about 25-30\% below) the 1992 levels, and there has been a declining trend in recent years.

## YFT-6. Management recommendations

The status of yellowfin showed some improvement between the 2003 and 2008 assessments, which is not surprising in that catches and fishing effort generally declined and there were small increases in catch rates observed for some longline fisheries over the past few years. Stock biomass in 2006 was estimated to be near the Convention Objective and fishing mortality rates somewhat below $\mathrm{F}_{\text {MSY. }}$. Continuation of current catch levels is expected to lead to a healthy biomass, somewhat above $\mathrm{B}_{\mathrm{MSY}}$, which should provide adequate safeguard against biomass falling below the Convention objective as long as fishing effort does not substantially increase. Effort increases on the order of about $10 \%$ above current levels (in order to achieve MSY) would be expected in the long run to increase yield by only about $1-4 \%$ over what could be achieved at current effective effort levels, but with substantially increased risk of biomass falling below the Convention objective. In addition, the Commission should be aware that increased harvest of yellowfin could have negative consequences for bigeye tuna in particular, and other species caught together with yellowfin in fishing operations taking more than one species. The Committee also continues to recommend that effective measures be found to reduce fishing mortality of small yellowfin, if the Commission wishes to increase long-term sustainable yield.

## ATLANTIC YELLOWFIN TUNA SUMMARY

|  | $\sim 130,600 \mathrm{t}^{\text {² }}$ (124,100-136,500) |
| :---: | :---: |
| Maximum Sustainable Yield (MSY) | $\sim 146,600 \mathrm{t}^{2}$ (128,200-152,500) |
| 2006 Yield ${ }^{3}$ | 108,160 t |
| Current Yield ${ }^{3}$ (2009) | 118,871 t |
| Replacement Yield (2006) | $\sim 130,000 \mathrm{t}$ |
| Relative Biomass $\mathrm{B}_{2006} / \mathrm{B}_{\mathrm{MSY}}{ }^{4}$ | 0.96 (0.72-1.22) |
| Relative Fishing Mortality: $\mathrm{F}_{\text {current(2006) }} / \mathrm{F}_{\text {MSY }}{ }^{4}$ | 0.86 (0.71-1.05) |
| $\mathrm{F}_{\text {current(2006) }} / \mathrm{F}_{0.1}{ }^{5}$ | 1.26 (1.11-1.44) |
| $\mathrm{F}_{\text {current }(2006)} / \mathrm{F}_{20 \% \text { SPR }}{ }_{5}^{5}$ | 0.81 (0.73-0.93) |
| $\mathrm{F}_{\text {current(2006) }} / \mathrm{F}_{30 \% \text { SPR }}{ }^{5}$ | 1.12 (1.01-1.29) |
| $\mathrm{F}_{\text {current(2006) }} / \mathrm{F}_{40 \% \text { SPR }}{ }^{5}$ | 1.52 (1.35-1.73) |

Management measures in effect:

- Effective fishing effort not to exceed 1992 level [Rec. 93-04].

NOTE: $\mathrm{F}_{\text {current(2006) }}$ refers to $\mathrm{F}_{2006}$ in the case of ASPIC, and the geometric mean of F across 2003-2006 in the case of VPA. As a result of the constant trend in recruitment estimated by the VPA model, $\mathrm{F}_{\mathrm{MAX}}$ is used as a proxy for $\mathrm{F}_{\text {MSY }}$ for VPA results.
${ }^{1}$ Estimates (with $80 \%$ confidence limits) based upon results of the age-structured model (VPA).
${ }^{2}$ Estimates (with $80 \%$ confidence limits) based upon results of the non-equilibrium production model (ASPIC).
${ }^{3}$ The assessment was conducted using the available catch data through 2006. Subsequent revisions have reduced reported catch levels slightly to $107,859 \mathrm{t}$.
${ }_{5}^{4}$ Median (25th-75th percentiles) from joint distribution of age-structured and production model bootstrap outcomes considered.
${ }^{5}$ Result exclusively from VPA and yield-per-recruit analyses.

YFT-Table 1. Estimated catches (t) of yellowfin tuna(Thunnus albacares) by area, gear and flag.

YFT-Figure 1 [a-f]. Geographical distribution of YFT catch by major gears and decade.

YFT-Figure 2. Estimated annual catch (t) of Atlantic yellowfin tuna by fishing gear, 1950-2009.

YFT-Figure 3. Yellowfin relative nominal catch rate trends from purse seine fleets, in weight. The Venezuelan trend (YFT-VEN-PS) reflects catches from the western Atlantic; the remaining two series YFT-TROP-PS (EU tropical) and YFT-EC-FAD-PS (EU tropical FAD sets) reflect catches in the eastern Atlantic.

YFT-Figure 4. Yellowfin standardized catch rate trends from baitboat fleets, in weight. The Brazilian trend (YFT-BRZ-BB) reflects catches from the western Atlantic; the remaining two series YFT-CAN-BB (Canary Islands) and YFT-EUDKR-BB (EU Dakar based) reflect catches in the eastern Atlantic.

YFT-Figure 5. Yellowfin standardized catch rate trends from longline fleets, in weight and numbers. The Japanese (YFT-JPN-LL) and Chinese Taipei (YFT-TAI-LL) trends reflect catches from throughout the Atlantic; the remaining series reflect catches in the western Atlantic. Series are identified using abbreviations for the flags; indices developed jointly include a Mexico-USA series (MEXUS) and a Brazil-Uruguay series (BRZURU).

YFT-Figure 6. Trend in yellowfin tuna average weight by gear group (top) and total (bottom) calculated from available catch-at-size data. Purse seine averages are calculated across all set types (floating object and free school).

YFT-Figure 7. Relative distribution of Atlantic yellowfin catches by age (0-5+) and year (bubble size is proportional to total catches), in number.

YFT-Figure 8. Estimates of historical MSY values for Atlantic yellowfin obtained through the age-structured model analysis, which considers the changes in selectivity that have occurred.

YFT-Figure 9. Stock status trajectories of $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ from age structured (VPA runs 5 and 10 ) and production model (ASPIC) analyses. VPA runs 5 and 10 estimate selectivity vectors for each abundance index using fleet-specific catch-at-age, differing only in that Run 5 estimates steeply domeshaped selectivity patterns for longline and EU tropical PS indices and Run 10 fixes these as flat-topped patterns. The age structured analysis started in 1970 and the production model in 1950. Current status is indicated by the large point at the end of each time-series.

YFT-Figure 10. Current status of yellowfin tuna based on age structured and production models. The median point estimate for each model is shown as a large diamond and the clouds of symbols depict the bootstrap estimates of uncertainty for the most recent year.

YFT-Figure 11. Summary of current status estimates for the yellowfin tuna stock based on age structured and production models making use of the catch and effort data through 2006.

YFT-Figure 12. Constant catch projection results using the results of age-structured (VPA) analyses.

YFT-Figure 13. Relationship between equilibrium yield ( $t$ ) and fishing mortality estimated from various models (VPA refer to age-structured models and PM refers to surplus production models). The X-axis has been scaled for each model such that a value of 1.0 represents that model's estimate of current (2006) fishing mortality.

### 8.2 BET- BIGEYE TUNA

The last stock assessment for bigeye tuna was conducted in 2010 through a process that included a data preparatory meeting in April and an assessment meeting in July. The last year fishery data used was 2009 but most indices of relative abundance stopped in 2008.

## BET-1. Biology

Bigeye tuna are distributed throughout the Atlantic Ocean between $50^{\circ} \mathrm{N}$ and $45^{\circ} \mathrm{S}$, but not in the Mediterranean Sea. This species swims at deeper depths than other tropical tuna species and exhibits extensive vertical movements. Similar to the results obtained in other oceans, pop-up tagging and sonic tracking studies conducted on adult fish in the Atlantic have revealed that they exhibit clear diurnal patterns: they are found much deeper during the daytime than at night. Spawning takes place in tropical waters when the environment is favorable. From nursery areas in tropical waters, juvenile fish tend to diffuse into temperate waters as they grow larger. Catch information from surface gears indicate that the Gulf of Guinea is a major nursery ground for this species. Dietary habits of bigeye tuna are varied and prey organisms like fish, mollusks, and crustaceans are found in their stomach contents. Bigeye tuna exhibit relatively fast growth: about 105 cm fork length at age three, 140 cm at age five and 163 cm at age seven. Bigeye tuna over 200 cm are relatively rare. Bigeye tuna become mature at about 3.5 years old. Young fish form schools mostly mixed with other tunas such as yellowfin tuna and skipjack. These schools are often associated with drifting objects, whale sharks and sea mounts. This association appears to weaken as bigeye tuna grow larger. Estimated natural mortality rates for juvenile fish, obtained from tagging data, were of a similar range as those applied in other oceans. Various pieces of evidence, such as a lack of identified genetic heterogeneity, the time-area distribution of fish and movements of tagged fish, suggest an Atlantic-wide single stock for this species, which is currently accepted by the Committee. However, the possibility of other scenarios, such as north and south stocks, should not be disregarded.

## BET-2. Fisheries indicators

The stock has been exploited by three major gears (longline, baitboat and purse seine fisheries) and by many countries throughout its range of distribution and ICCAT has detailed data on the fishery for this stock since the 1950s. Scientific sampling at landing ports for purse seine vessels of the EU and associated fleets have been conducted since 1980 to estimate bigeye tuna catches (BET-Figure 1, BET-Table 1). The size of fish caught varies among fisheries: medium to large for the longline fishery, small to large for the directed baitboat fishery, and small for other baitboat and for purse seine fisheries.

The major baitboat fisheries are located in Ghana, Senegal, the Canary Islands, Madeira and the Azores. The tropical purse seine fleets operate in the Gulf of Guinea and off Senegal in the East Atlantic and off Venezuela in the West Atlantic. In the eastern Atlantic, these fleets are comprised of vessels flying flags of Ghana, EU-France, EU-Spain and others which are mostly managed by EC companies. In the western Atlantic the Venezuelan fleet dominates the purse-seine catch of bigeye tuna. While bigeye tuna is now a primary target species for most of the longline and some baitboat fisheries, this species has always been of secondary importance for the other surface fisheries. In the surface fishery, unlike yellowfin tuna, bigeye tuna are mostly caught while fishing on floating objects such as logs or man-made fish aggregating devices (FADs). During 2009, landings in weight of bigeye tuna caught by the longline fleets of Japan and Chinese Taipei, and the purse seine and baitboat fleets of the EU and Ghana represented $75 \%$ of the total bigeye tuna catch.

The total annual Task I catch (BET-Table 1, BET-Figure 2) increased up to the mid-1970s reaching 60,000 t and fluctuated over the next 15 years. In 1991, catch surpassed $95,000 \mathrm{t}$ and continued to increase, reaching a historic high of about $133,000 \mathrm{t}$ in 1994. Reported and estimated catch has been declining since then and fell below $100,000 \mathrm{t}$ in 2001 . This gradual decline in catch has continued, although with some fluctuations from year to year, until the most recent year of data 2009. The preliminary estimate for 2009 is $86,011 \mathrm{t}$, the highest value in the last five years. This estimate includes preliminary estimates made for a few fleets that have not yet provided data to ICCAT.

After the historic high catch in 1994, all major fisheries exhibited a decline of catch while the relative share by each fishery in total catch remained relatively constant. These reductions in catch are related to declines in fishing fleet size (longline) as well as decline in CPUE (longline and baitboat). The number of active purse seiners declined by more than half from 1994 until 2006, but then increased since 2007 as some vessels returned
from the Indian Ocean to the Atlantic. The number of purse seiners operating in 2009 and 2010 was similar to the number operating in 2003-04 (SKJ-Figure 6).

IUU longline catches were estimated from Japanese import statistics but the estimates are considered uncertain. These estimates indicate a peak in unreported catches of $25,000 \mathrm{t}$ in 1998 and a quick reduction thereafter The Committee expressed concern that historical catches from illegal, unreported and unregulated (IUU) longliners that fly flags of convenience from the Atlantic might have been poorly estimated. The magnitude of this problem has not yet been quantified, because available statistical data collection mechanisms are insufficient to provide alternative means to calculate unreported catch.

Significant catches of small bigeye tuna continue to be channeled to local West African markets and sold as "faux poissons" in ways that make their monitoring and official reporting challenging. Monitoring of such catches has progressed in some countries but there is still a need for a coordinated approach that will allow ICCAT to properly account for these catches and thus increase the quality of the basic catch data available for assessments.

Mean average weight of bigeye tuna decreased prior to 1998 but has been relative stable, at around 10 kg during the last decade (BET-Figure 3). This weight, however, is quite different according to the fishing gear, around 62 kg for longliners, 7 kg for bait boats, and 4 kg for purse seiners. In the last ten years all longline fleets have shown increases in mean weight of bigeye tuna caught, with the average longline-caught fish increasing from 40 kg to 60 kg between 1999 and 2009. During the same period purse seine-caught bigeye tuna had weights between 3 kg and 4 kg , with the exception of 2009 when the average weight was 4.5 kg . Bigeye tuna caught since 2004 in free schools are significantly larger than in previous years. Since FAD catches began being identified separately in 1991 by EU and associated purse seine fleets, the majority ( $75 \%-80 \%$ ) of bigeye tuna are caught in sets associated with FADs. Similarly baitboat-caught bigeye tuna weighted between 6 and 10 kg over the same period, showing greater interannual variability in fish weight than longline or purse seine caught fish.

## BET-3. State of the stock

The 2010 stock assessment was conducted using similar assessment models to those used in 2007 but with updated data and a few new relative abundance indices and data. In general, data availability has continued to improve, notably with the addition of relative abundance indices for an increasing number of fleets. There are still missing data on detailed fishing and fish size from certain fleets. In addition, there are a number of data gaps on the activities of IUU fleets (e.g., size, location and total catch). All these problems forced the committee to assume catch-at-size for an important part of the overall catch.

Three types of indices of abundance were used in the assessment. A number of indices were directly developed by national scientists for selected fleets for which data was available at greater spatial and or temporal resolution to that available in the ICCAT databases. These indices represented data for seven different fleets, all of them longline fleets, except for one baitboat fleet (BET-Figure 4). Other indices were estimated by the committee from data available within the ICCAT databases. These two types of indices were used for age-structured assessment models. Finally, a series of combined indices (BET-Figure 5) were calculated by the committee by synthesizing the information existing in individual indices for the seven fleets mentioned above. The later were used to fit production models.

Consistent with previous assessments of Atlantic bigeye tuna, the results from non-equilibrium production models are used to provide the basic characterization of the status of the resource. Results were sensitive to the combined abundance index trends assumed. As the relative likelihoods of each trend could not be estimated, results were developed from the joint distribution of model run results using each of three alternative combined indices. The plausible range of MSY estimated from the joint distribution using three types of abundance indices was between 78,700 and 101,600 tons ( $80 \%$ confidence limits) with a median MSY of $92,000 \mathrm{t}$. In addition, these estimates reflect the current relative mixture of fisheries that capture small or large bigeye tuna; MSY can change considerably with changes in the relative fishing effort exerted by surface and longline fisheries. Historical estimates show large declines in biomass and increases in fishing mortality, especially in the mid 1990s when fishing mortality exceeded $\mathrm{F}_{\text {MSY }}$ for several years. In the last five or six years there have been possible increases in biomass and declines in fishing mortality (BET-Figure 6). The biomass at the beginning of 2010 was estimated to be at between 0.72 and 1.34 ( $80 \%$ confidence limits) of the biomass at MSY, with a median value of 1.01 and the 2009 fishing mortality rate was estimated to be between $0.65-1.55$ ( $80 \%$ confidence limits) with a median of 0.95 . The replacement yield for the year 2011 was estimated to be about MSY.

The Committee notes, as it did in previous assessments, that there is considerable uncertainty in the assessment of stock status and productivity for bigeye tuna. There are many sources of uncertainty including which method represents best the dynamics of the stock, which method is supported more by the available data, which relative abundance indices are appropriate to be used in the assessment, and what precision is associated with the measurement/calculation of each of the model inputs. In general, data availability has improved since 2007 but there is still a lack of information regarding detailed fishing effort and catch-at-size data from certain fleets. This, combined with the lack of detailed historical information on catch and fishing activities of IUU fleets (e.g., size, location and total catch), forces the Committee to make many assumptions about the catch-at-size for an important part of the overall catch. In order to represent this uncertainty the Committee decided to combine sensitivity runs from a range of method/data combinations. There are differences in the estimates of management benchmarks, including the estimates of the current biomass and fishing mortality, depending on both the method used as well as the input data used (BET-Figure 7).

## BET-4. Outlook

The outlook for Atlantic bigeye tuna, considering the quantified uncertainty in the 2010 assessment, is presented in BET-Table 2 and BET-Figure 8, which provide a characterization of the prospects of the stock achieving or being maintained at levels consistent with the Convention Objective, over time, for different levels of future constant catch. It is noteworthy that the modeled probabilities of the stock being maintained at levels consistent with the Convention Objective over the next five years are about $60 \%$ for a future constant catch of $85,000 \mathrm{t}$. Higher odds of rebuilding to and maintaining the stock at levels that could produce MSY are associated with lower catches and lower odds of success with higher catches than such constant catch (BET-Figure 9). It needs to be noted that projections made by the Committee assume that future constant catches represent the total removals from the stock, and not just the TAC of $85,000 \mathrm{t}$ established by ICCAT [Rec. 09-01]. Catches made by other fleets not affected by [Rec. 09-01] need to be added to the $85,000 \mathrm{t}$ for comparisons with the future constant catch scenarios contemplated in BET-Table 2. Furthermore, any future changes in selectivity due to changes in the ratios of relative mortality exerted by the different fleets - such as an increase in the relative mortality of small fish - will change and add to the uncertainty of these projections.

## BET-5. Effects of current regulations

During the period 2005-2008 an overall TAC for major countries was set at $90,000 \mathrm{t}$. The TAC was later lowered [09-01] to 85,000 t. Estimates of catch for 2005-2009 (BET-Table 1) seem to have been always lower than the corresponding TAC.

Concern over the catch of small bigeye tuna partially led to the establishment of spatial closures to surface fishing gear in the Gulf of Guinea [Rec. 04-01 and 08-01] The Committee examined trends in average bigeye tuna weight as a broad indicator of the effects of such closures. Although there have been significant changes in the average size of bigeye tuna caught since 2004 by certain fleets, such as increases in average size of fish caught by purse seiners operating in free schools and by longliners, it cannot be quantified whether changes are the result of spatial closures. The Committee also analyzed the ICCAT conventional tag database for evidence of an effect of spatial closures. Again, this analysis failed to provide any conclusive evidence in support of the hypothesis that spatial closures led to a reduction in the fishing mortality of juvenile bigeye tuna.

## BET-6. Management recommendations

Projections indicate that catches reaching $85,000 \mathrm{t}$ or less will promote stock growth and further reduce the future chances that the stock will not be at a level that is consistent with the convention objectives. The Commission should be aware that if major countries were to take the entire catch limit set under Recommendations 04-01 and 09-1 and other countries were to maintain recent catch levels, then the total catch could well exceed $100,000 \mathrm{t}$. The Committee recommends that the Commission sets a TAC at a level that would provide a high probability of maintaining at or rebuilding to stock levels consistent with the Convention objectives. In considering the uncertainty in assessment results, the Committee believes that a future total catch of $85,000 \mathrm{t}$ or less would provide such high probability.

The assessment and subsequent management recommendations are conditional on the reported and estimated history of catch for bigeye tuna in the Atlantic. The Committee reiterates its concern that unreported catches,
including those part of the "faux poisson" category, from the Atlantic might have been poorly estimated. There is a need to expand current statistical data collection mechanisms to fully investigate any evidence of significant catches that have been unreported.

|  | ATLANTIC BIGEYE TUNA SUMMARY |
| :--- | :---: |
| Maximum Sustainable Yield | $78,700-101,600 \mathrm{t}(\text { median } 92,000 \mathrm{t})^{1,2}$ |
| Current (2009) Yield ${ }^{1}$ | $86,011 \mathrm{t}^{2,3}$ |
| Replacement Yield (2011) | $64,900-94,000(\text { median } 86,000 \mathrm{t})^{1,2}$ |
| Relative Biomass ( $\left.\mathrm{B}_{2009} / \mathrm{B}_{\mathrm{MSY}}\right)$ | $0.72-1.34(\text { median } 1.01)^{1,2}$ |
| Relative Fishing Mortality |  |
| $\quad \mathrm{F}_{2009} / \mathrm{F}_{\mathrm{MSY}}$ | $0.65-1.55(\text { median } 0.95)^{1,2}$ |

Conservation \& management measures in effect:
[Rec. 09-01], para. 1 of [Rec. 06-01] and [Rec. 04-01].

- Total allowable catch for 2010 is set at $85,000 \mathrm{t}$ for Contracting Parties and Cooperating non-Contracting Parties, Entities or Fishing Entities.
- Limits on numbers of fishing vessels less than the average of 1991 and 1992.
- Specific limits of number of longline boats; China (45), Chinese Taipei (67), Philippines (10).
- Specific limits of number of purse seine boats; Panama (3).
- No purse seine and baitboat fishing during November in the area encompassed by $0^{\circ}-5^{\circ} \mathrm{N}$ and $10^{\circ} \mathrm{W}-20^{\circ} \mathrm{W}$.

[^0]BET-Table 1. Estimated catches (t) of bigeye tuna(Thunnus obesus) by area, gear and flag, used in the assessment (2009 catches in Italic are estimations adopted by the WG).

BET-Figure 6. Trajectories of $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ estimated from the logistic production model. Lines represent the $80 \%$ percentile of bootstrap results and thicker line the median.

BET-Figure 7. Kobe plot from combined examinations of assessment models. Shaded lines shown represent the $80 \%$ confidence limits for the historical trajectory (1950-2009) and solid line represents the median estimated from the logistic production model. Points depict uncertainty in current status not considered by the bootstrapping of the logistic production model (estimates of $\mathrm{F}_{2009} / \mathrm{F}_{\mathrm{MSY}}$ and $\mathrm{B}_{2009} / \mathrm{B}_{\text {MSY }}$ for each of the sensitivity trials from the other models considered in the assessment).

BET-Figure 8. Biomass projections ( $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ ) for bigeye tuna for 2011-2021. Each panel corresponds to a different level of future constant catch from 60,000 to 110,000 tons. Thick lines represent median of all combined runs and thinner lines the 10 and 90 percentiles.

BET-Figure 9. Kobe matrix plot showing probabilities of the stock being above $\mathrm{B}_{\text {MSY }}$ and fishing at levels below $\mathrm{F}_{\text {MSY }}$ in a given year for a future constant catch (TAC). Projections were calculated from results of the combination of the three logistic production model runs used as the basis of the assessment. The colors represent modeled probabilities: red, $<50 \%$, yellow, $50-75 \%$ and green, $>75 \%$. The $60 \%$ probability isopleth is also shown as a black line.

### 8.3 SKJ - SKIPJACK TUNA

Stock assessments for eastern and western Atlantic skipjack were conducted in 2008 using available catches to 2006. Skipjack had only been assessed previously in 1999. Consequently, this report includes the most recent information on the state of the stocks on this species.

## SKJ-1. Biology

Skipjack tuna is a gregarious species that is found in schools in the tropical and subtropical waters of the three oceans (SKJ-Figure 1). Skipjack is the predominant species under FADs where it is caught in association with juvenile yellowfin tuna, bigeye tuna and with other species of epipelagic fauna. One of the characteristics of skipjack is that from the age of one it spawns opportunistically throughout the year and in vast sectors of the ocean. A recent analysis of tagging data from the eastern Atlantic confirmed that the growth of skipjack varies according to the latitude. However, this difference in the growth rate is not as great as that which had been previously estimated.

The increasing use of fish aggregation devices (FADs) since the early 1990s, have changed the species composition of free swimming schools. It is noted that, in effect, the free schools of mixed species were considerably more common prior to the introduction of FADs. Furthermore, the association with FADs may also have an impact on the biology (food intake, growth rate, plumpness of the fish) and on the ecology (displacement rate, movement orientation) of skipjack and yellowfin (ecological trap concept).

## SKJ-2. Fisheries indicators

The total catches obtained in 2009 in the entire Atlantic Ocean (including estimates of skipjack in the fauxpoisson landed in Côte d'Ivoire by the EU-purse seiners) were close to 148,000 t (SKJ-Table 1, SKJ-Figure 2) which represents the catch average of the last five years.

The numerous changes that have occurred in the skipjack fishery since the early 1990s (such as the progressive use of FADs and the increase of the fishing area towards the west) have brought about an increase in skipjack catchability and in the biomass proportion that is exploited. At present, the major fisheries are the purse seine fisheries, particularly those of EU-Spain, Ghana, Panama, EU-France and Netherlands Antilles, followed by the baitboat fisheries of Ghana, EU-Spain, EU-Portugal and EU-France. The preliminary estimates of catches made in 2009 in the East Atlantic amounted to $122,000 \mathrm{t}$, that is, a catch on the order of the average of 2004-2008 (SKJ-Figure 3). In recent years, the seasonal fishing by European purse seiners on free schools, off Senegal, has decreased sharply (SKJ-Figure 1) and consequently, the proportion of the catches on floating objects has continued to increase, reaching slightly more than $90 \%$ of the catches (SKJ-Figure 4).

The estimate of the average discard rate of skipjack tuna under FADs from data collected since 2001 by observers on-board Spanish purse seiners operating in the East Atlantic has been confirmed by the two new studies conducted on board French purse seiners (estimated at 42 kg per ton of skipjack landed). Furthermore, this last study showed that the amount of small skipjack (average size 37 cm FL) landed in the local market of Abidjan in Côte d'Ivoire as faux-poisson is estimated at 235 kg per ton of skipjack landed (i.e. an average of 6,641 t/year between 1988 and 2007, SKJ-Figure 5). The Committee integrated these estimates in the reported historical catches for the EU-purse seiners since 1981, as well as in the catch-at-size matrix.

In the West Atlantic, the major fishery is the Brazilian baitboat fishery, followed by the Venezuelan purse seine fleet. Estimates of catches in 2009 in the West Atlantic amounted to $26,000 \mathrm{t}$, i.e. a stable catch compared to the average observed for recent years (SKJ-Figure 6).

It is difficult to estimate effective fishing effort for skipjack tuna in the East Atlantic. Nominal purse seine effort, expressed in terms of carrying capacity, has decreased regularly since the mid-1990s up to 2006. However, due to acts of piracy in the Indian Ocean, many European Union purse seiners have transferred their effort to the East Atlantic. This new situation, which added to the presence of three new purse seiners operating from Tema (Ghana), has considerably increased the carrying capacity of this fishing gear (SKJ-Figure 7). The number of EU purse seiners in the East Atlantic follows this trend but seems to have stabilized in 2010, according to the preliminary estimates. On the other hand, baitboat nominal effort has remained stable for more than 20 years.

It is considered that the increase in fishing power linked to the introduction of innovation technologies on board the vessels as well as to the development of fishing under floating objects has resulted in an increase in the efficiency of the various fleets, since the early 1980s. In addition to the use of an average $3 \%$ annual increase in skipjack catchability to account for these changes, a new analysis has been conducted by fixing MSY and K at levels that agree with estimates made during previous stock assessments. This method provides a range of increase in catchability from 1 to $13 \%$ per year. It is unclear, however, whether these estimates reflect technological changes only, or also in the availability of the fish (e.g., resulting from an expansion of the surface exploited over the years; SKJ-Figure 8). The recent increase in the area explored successfully which corresponds to the extension of the fishery towards the central west Atlantic and off Angola should also be noted.

The significant increase in the estimates of total mortality ( $Z$ ) between the early 1980s and the end of the 1990s obtained from different methods, such as the tag-recovery model, the catch curves by size and the average size observed in the yearly catches, supports this hypothesis. The change in the selectivity pattern observed for the purse seine fishery suggests that this fleet is mainly targeting juvenile tunas. The comparison of the size distributions of skipjack for the East Atlantic between the periods prior to, and following the use of FADs, also reinforces this interpretation insofar as an increase is observed in the proportion of small fish in the catches, as shown by the change of the average weight over the years (SKJ-Figure 9). Generally, it is noted that the average weight observed in the east Atlantic (close to 2 kg ) is much lower than the estimates given in the other oceans (closer to 3 kg ).

The regular increase in fishing pressure observed for the other indicators is confirmed up to about 1995, then the decline in apparent Z (a trend also observed for yellowfin) could be a consequence of the moratoria on floating objects which has mainly affected skipjack (SKJ-Figure 10).

With respect to the West Atlantic, the fishing effort of the Brazilian baitboats (i.e., the major skipjack fishery in this region) seems to be stable over the last 20 years.

## SKJ-3. State of the stocks

In all the oceans and consequently in all the tuna RFMOs, the traditional stock assessment models have been difficult to apply to skipjack because of their particular biological and fishery characteristics (on the one hand, continuous spawning, areal variation in growth and non-directed effort, and on the other, weak identified cohorts). In order to overcome these difficulties, several different assessment methods which accommodate expert opinion and prior knowledge of the fishery and biological characteristics of skipjack have been carried out on the two stocks of Atlantic skipjack. Several fishery indictors were also analyzed for evidence of changes in the state of the stock over time.

Although the fisheries operating in the east have extended towards the west beyond $30^{\circ} \mathrm{W}$ longitude, the Committee decided to maintain the hypothesis in favor of two distinct stock units, based on available scientific studies. However, taking into account the state of current knowledge of skipjack tuna migrations and the geographic distances between the various fishing areas (SKJ-Figure 1 and SKJ-Figure 11), the use of smaller stock units continues to be the envisaged working hypothesis.

## Eastern stock

The Committee analyzed two standardized indices from the EU-purse seine fishery: An index accounts for skipjack caught in free school in the Senegalese area during the second quarter of the year and the second index characterizing small fish captured under FADs in the equatorial area (SKJ-Figure 12). In previous meetings of the Tropical Tunas Species Group it was confirmed that the increase in CPUE of the European purse seiners in the late 1990s was due, mainly, to the increase in the catches of positive sets under FADS (SKJ-Figure 13). Furthermore, the regular increase in the skipjack yields of the baitboats based in Senegal (contrary to the other two tropical tuna species) may only have been the result of an increase in catchability linked to the adoption of the so-called "baitboat associated school" fishing towards the mid-1980s (SKJ Figure 14). Furthermore, no marked trend has been observed for the Canary Islands baitboats as well as for a peripheral fishery such as the Azorean baitboat fishery. The fact that a reduction in abundance for a local segment of the stock would have little repercussion on abundance in other areas, leads to suppose that only a minor proportion of skipjack carry out extensive migrations between areas (SKJ-Figure 11; cf. notion of stock viscosity). This assumption was reinforced by a recent tagging study on growth variability of skipjack between two eastern Atlantic regions
divided by $10^{\circ} \mathrm{N}$ latitude, which were established on the basis of their low amount of mixing (only $0.9 \%$ of the tagged fish crossed this latitudinal limit).

A new bayesian method, using only catch information (under a Schaefer-type model parameterization), estimated the MSY at $143,000-156,000 \mathrm{t}$, a result which agrees with the estimate obtained by the modified Grainger and Garcia approach: 149,000 t.

In addition, two non-equilibrium surplus biomass production models (a multi-fleets model and a Schaefer-based model) were applied for 8 time series of CPUEs, and for a combined CPUE index weighted by fishing areas. To account for the average increase in catchability of purse seine fisheries, a correction factor of $3 \%$ per year was applied to the CPUE series. As for the bayesian model application that only uses catches, different working hypothesis were tested on the distribution of the priors of the two surplus production models (i.e., the growth rate, the carrying capacity, the catchability coefficient of each fleet, etc.). In general, the range of plausible MSY values estimated from these models ( $155,000-170,000 \mathrm{t}$ ) were larger than in the bayesian model based on catches. The Committee stated the difficulty to estimate MSY under the continuous increasing conditions of the exploitation plot of this fishery (one-way of the trajectory to substantially weaker effort values) and which as a result, the potential range distribution of some priors needs to be constrained (e.g., for growth rate, or for the shape parameter of the generalized model).

While caution is needed as regards to the generalization of the diagnosis on the stock status of the overall components of this stock in the East Atlantic, due to the moderate mixing rates that seem to occur among the different sectors of this region, it is unlikely that skipjack be exploited in the eastern Atlantic (SKJ-Figure 15).

## Western stock

The standardized CPUEs of Brazilian baitboats remain stable while that of Venezuelan purse seiners and USA rod and reel decreased in recent years (SKJ-Figure 16). This decrease, also observed in the CPUE time series for Venezuelan purse seine, could be linked to specific environmental conditions (high surface temperatures, lesser accessibility of prey). The average weight of skipjack caught in the western Atlantic is higher than in the east (3 to 4.5 kg vs. 2 to 2.5 kg ), at least for the Brazilian baitboat fishery.

The assessment model from catches estimated MSY at around $30,000 \mathrm{t}$ (similar to the estimate provided by the Grainger and Garcia approach) and the Bayesian surplus model (Schaefer formulation) at 34,000 t.

The Group attempted several sensitivity analyses for values of natural mortality with Multifan-CL. For this stock only the three fisheries mentioned above were considered. The final estimate of MSY converges also at about: $31,000-36,000 \mathrm{t}$. It must be stressed that all of these analyses correspond to the current geographic coverage of this fishery (i.e., relatively coastal fishing grounds due to the deepening of the thermocline and of the oxycline to the East).

For the western Atlantic stock, in the light of the information provided by the trajectories of $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$, it is unlikely that the current catch is larger than the current replacement yield (SKJ-Figure 17).

## SKJ-4. Effects of current regulations

There is currently no specific regulation in effect for skipjack tuna.
However, with the aim of protecting juvenile bigeye tuna, the French and the Spanish boat owners voluntarily decided to apply a moratorium for fishing under floating objects between November and the end of January for the 1997-1998 and 1998-1999 periods. The Commission implemented a similar moratorium from 1999 to January 2005. This moratorium has had an effect on skipjack catches made with FADs.

On the basis of a comparison of average catches between 1993-1996, prior to the moratoria, and those between the 1998-2002 period, the average skipjack catches between November and January for the purse seine fleets that applied the moratoria, were reduced by $64 \%$. During that period (1998-2002), the average annual skipjack catches by purse seine fleets that applied the moratoria decreased by $41 \%$ ( $42,000 \mathrm{t}$ per year). However, this decrease is possibly a combined result of the decrease in effort and the impact of the moratoria (the average annual catch per boat decreased only $18 \%$ between these two periods).

The repealing in 2006 of Recommendation [Rec. 05-01] on the 3.2 kg minimum size limit on yellowfin tuna [Rec. 72-01] (although it remained in force in 2005) and the establishment of a time/area closure of the surface fishery [Rec. 04-01], which replaces the old strata relative to the moratorium on catches under floating objects, are regulatory measures whose effects were analyzed during the Species Group meeting.

Considering that the new closed area is much smaller in time and surface than the previous moratorium time/area, and is located in an area which historically has lower effort anyway, this regulation is likely to be less effective in reducing the overall catches of small bigeye (the species for which the regulation was applied) by the surface fishery. When the fishing effort for the EU purse seine fleet was at its maximum value (period 19941996, i.e., before the implementation of the first moratorium), the skipjack catch from this fleet within the time and area limits defined by Rec. 04-01, was only on average at $7,180 \mathrm{t}$ (i.e., $7.5 \%$ of the total skipjack catch from the EU purse seiners).

## SKJ-5. Management recommendations

Although the Committee makes no management recommendations in this respect, catches should not be allowed to exceed MSY. The Commission should be aware that increasing harvests and fishing effort for skipjack could lead to involuntary consequences for other species that are harvested in combination with skipjack in certain fisheries.

## ATLANTIC SKIPJACK TUNA SUMMARY

|  | East Atlantic | West Atlantic |
| :--- | :--- | :--- |
| Maximum Sustainable Yield (MSY) | Around 143,000-170,000 t | Around 30,000-36,000 t |
| Current (2009) Yield ${ }^{1}$ | $122,000 \mathrm{t}$ | $26,000 \mathrm{t}$ |
| Current Replacement Yield | Somewhat higher than 122,000 t | Somewhat higher than 26,000 t |
| Relative Biomass ( $\left.\mathrm{B}_{2008} / \mathrm{B}_{\mathrm{MSY}}\right)$ | Most likely>1 | Most likely>1 |
| Relative Fishing Mortality: $\left(\mathrm{F}_{2008} / \mathrm{F}_{\mathrm{MSY}}\right.$ | Most likely<1 | Most likely<1 |
| Management measures in effect | Rec. 04-01 (effective 2005) ${ }^{2}$ | None |

${ }^{1}$ Reports for 2009 should be considered provisional.
${ }^{2}$ Although this time-area measure was implemented to reduce mortality on bigeye juvenile tuna, a total area closure has the expected effects on all the tropical tuna species.

1) The estimation of Cote d'Ivoire corresponds to the average of the five previous years.
2) The estimation for mixed flag (Fra+Spa) corresponds to the faux poisson SKJ catches for the two fleets only.

SKJ-Figure 1. (A) Distribution of skipjack catches in the Atlantic, by gear, for the period 2000-2008 (upper panel); The high catch shown in the Gulf of Guinea is due to the catches by Ghana that are taken in the same statistical area lack detailed information. (B) Skipjack catches made by European purse seiners (about 75\% of the total catches) 1996-2005 (lower left panel) and 2006-2009 (lower right panel) showing the withdrawal from the Senegal zone due to non-renewal of the fishing agreements.

SKJ-Figure 2. Total catch (t) for skipjack tuna in the Atlantic Ocean and by stocks (East and West) between 1950 and 2009. Estimates of skipjack in the "faux poissons" landed in Côte d'Ivoire were included in the skipjack trade catches in the East Atlantic (only catches to 2006 were considered for the stock assessment).

SKJ-Figure 3. Skipjack catches in the eastern Atlantic, by gear (1950-2009).

SKJ-Figure 4. Changes in the proportion of catches made by European purse seiners under FADs.

SKJ-Figure 5. Cumulative estimated landings of "faux poissons" for the three main species of tropical tunas in the local market of Abidjan (Côte d'Ivoire).

SKJ-Figure 6. Skipjack catches in the western Atlantic, by gear (1950-2009).

SKJ-Figure 7. Changes over time in the carrying capacity (corrected by time at sea) of purse seiners and baitboats operating in the eastern Atlantic (1971-2009) and in number of boats for the European purse seiners (value estimated for 2010).

SKJ-Figure 8. Number of $1^{\circ} \mathrm{x} 1^{\circ}$ squares with catch of skipjack for the purse seiners operating in the eastern Atlantic (1969-2009). The increase observed in 1991 could be due to a modification of the species composition correction procedure of the catches implemented at this date (skipjack catches could have been attributed to squares which were not included until then). On the other hand, the recent increase in the area searched successfully corresponds to the extension of the fishery towards the western central Atlantic and off Angola.

## SKJ mean weights

SKJ-Figure 9. Changes in time of the mean weight of the skipjack landed (non standardized) by major fisheries in the eastern Atlantic.

SKJ-Figure 10. Changes over time in the apparent total mortality Z, calculated based on Beverton and Holt’s equation, for the three main tropical tuna species in the Atlantic Ocean. YFT = yellowfin, BET = bigeye, $\mathrm{SKJ}=$ Eastern skipjack. The size at which the fish are fully recruited was fixed at 50 cm (FL).

SKJ-Figure 11. Distribution of tagged and released SKJ (left panel) and apparent movements from geographic positions of recaptured fish (right panel).

SKJ-Figure 12. Standardized skipjack CPUE for EU purse seiners in the eastern Atlantic Ocean. Free $=$ free school off Senegal; FAD = schools associated with fish aggregating devices in the equatorial areas.

SKJ-Figure 13. Changes in nominal CPUE for the European purse seiners in the eastern Atlantic (1970-2009). Free $=$ free schools ( $t / f$. day) off Senegal; FADs $=$ schools associated with fish aggregating devices ( $t /$ successful set) in the equatorial area.

SKJ-Figure 15. Eastern skipjack stock status: trajectories of $B / B_{M S Y}$ and $F / F_{\text {MSY }}$ from the Bayesian surplus production model (Schaefer type), and from the generalized multi-fleets dynamic model.

SKJ-Figure 16. Standardized CPUEs of Brazilian baitboats, U.S. rod and reel recreational fleets and nonstandardized CPUE of the Venezuelan purse seiners in the western Atlantic Ocean.

SKJ-Figure 17. Western skipjack stock status: trajectories of $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\text {MSY }}$ from the Bayesian surplus production model (Schaefer type) and from Multifan-CL.

### 8.4 ALB - ALBACORE

The status of the North Atlantic albacore stock is based on the most recent analyses conducted in July 2009 by means of applying statistical modelling to the available data up to 2007. Complete information on the assessment can be found in the Report of the 2009 ICCAT Albacore Stock Assessment Session (SCRS/2009/015, Anon., 2010).

The status of the South Atlantic albacore stock is based on the 2007 assessment using available data up to 2005. Complete information is found in the Report of the 2007 ICCAT Albacore Stock Assessment Session (SCRS/2007/015).

This year a Mediterranean Albacore Data Preparatory Meeting was held, following the 2009 recommendations of the Albacore Species Group. However, no assessment was conducted. Complete information is found in document SCI-032.

## ALB-1. Biology

Albacore is a temperate tuna widely distributed throughout the Atlantic Ocean and Mediterranean Sea. On the basis of the biological information available for assessment purposes, the existence of three stocks is assumed: northern and southern Atlantic stocks (separated at $5^{\circ} \mathrm{N}$ ) and Mediterranean stock (ALB-Figure 1). However, the hypothesis that various sub populations of albacore have been exploited in the North Atlantic (Aloncle \& Delaporte 1973) remains of potential interest in the stock assessment. Likewise, there is likely intermingling of Indian Ocean and South Atlantic immature albacore which needs further research.

Scientific studies on albacore stocks, in the north Atlantic as well as in the North Pacific, have been showing that trends in environmental variability may have a serious potential impact on albacore stocks, affecting fisheries by changing the fishing grounds as well as recruitment levels and potential MSY of the stocks. Those unexplored aspects might explain changes in fisheries and the apparent decline in the estimated recruitment which are demanding focussed research.

The expected life-span for albacore is around 15 years. While albacore is a temperate species, spawning occurs in tropical waters. A new weight-at-length relationship for the western Atlantic fishery was presented that showed to be different from that presently used for the northern stock. Present available knowledge on habitat distribution according to size, spawning areas and maturity estimates of Atlantic albacore is based on limited studies from past decades.

An exception is a revised, new growth equation for the South stock. For Mediterranean albacore, the available biological knowledge has not yet been fully analyzed by the Albacore Species Group. More information on albacore biology and ecology is published in the ICCAT Manual.

## ALB-2. Description of fisheries or fisheries indicators

## North Atlantic

The northern stock is exploited by surface fisheries targeting mainly immature and sub-adult fish ( 50 cm to 90 cm FL) and longline fisheries targeting immature and adult albacore ( 60 cm to 130 cm FL). The main surface fisheries are carried out by EU fleets (Ireland, France, Portugal and Spain) in the Bay of Biscay, in the adjacent waters of the northeast Atlantic and in the vicinity of the Canary and Azores Islands in summer and autumn. The main longline fleet is the Chinese Taipei fleet which operates in the central and western North Atlantic year round. However, Chinese Taipei fishing effort decreased in late 1980s due to a shift towards targeting on tropical tuna, then continued at this lower level to the present. Over time, the relative contribution of different fleets to the total catch of North Atlantic albacore has changed, which resulted in differential effects on the age structure of the stock.

The historical time series of catch was extended back to 1930 for the troll fishery after revision of data for the assessment. Total reported landings for the North Atlantic generally began to decline after 1986, largely due to a reduction of fishing effort by the traditional surface (troll and baitboat) and longline fisheries (ALB-Table 1; ALB-Figure 2a). Some stabilization was observed in the 1990s, mainly due to increased effort and catch by new surface fisheries (driftnet and mid-water pair pelagic trawl) with a maximum catch in 2006 at $36,989 \mathrm{t}$ and since then a decreasing trend of catch is observed in the North Atlantic.

The total catch in 2009 was 15,364 t, representing a decrease of $25 \%$ compared to the 2008 yield and a larger decrease from the 2006 peak catch $(36,989 \mathrm{t})$. The catch in 2009 was the lowest recorded in the time series since 1950.

The surface fisheries accounted for the bulk of the total catch with 12,911 t reported in 2009 (81\%) (ALB-Table 1). The reported catch for EU-France in 2009 was $1,122 \mathrm{t}$, a decrease from 2008. The reported catch for EUSpain in 2009 was 9,376 t from the troll fleet and baitboat fleets in the summer Cantabrian Sea fishery (SCRS/2010/145) and the baitboat fishery in the Canary Islands (SCRS/2010/144). It represents a decrease from the 2008 catch. In contrast, EU-Ireland 2009 reported catches had increased compared to 2008 and by two and a half fold from 2007. The EU-Portugal catch from the baitboat fishery in 2009 was 108 t , a five-fold decrease from 2008.

Standardized catch rates of fish ages 1 to 4 from the Spanish troll fleet were updated to 2009 (SCRS/2010/146). Albacore age 1 showed an increasing trend peaking in 2005 and 2006, fluctuating since then and a decrease in 2009. Age 2 albacore showed an increasing trend since 2004 with peaks in 2006 and 2008 and a decreasing trend in 2009. In the case of age 3, there is a continued upward trend from 2007 to 2009. Catch rates of the Irish midwater pelagic trawl fleet showed a steep decline in 2007 compared to the higher estimates for 2005 and 2006.

In total, the 2009 longline catches were similar to 2007. The Chinese Taipei catch in 2009 was 863 t , a decrease of 244 t as compared with that of 2008. The decrease in catch mainly stemmed from a reduction in fishing effort. Japan takes albacore as by-catch with longline gear. The Japanese longline catch reached 285 t in 2009, which represented a $30 \%$ decrease from 2008. The catch fluctuated from around 300 t to $1,300 \mathrm{t}$ in the last decade. Recent catch rates from the Chinese Taipei longline fishery in 2008 showed the same level as in 2007 (SCRS/2009/105).

The trend in mean weight for all surface fleets (baitboat, troll, mid-water, pair pelagic and other surface) from 1975 to 2007 showed a stable trend with an average of 7 kg (range:4-10). For longline fleets from 1975 to 2005 the mean weight was also relatively stable with an average of 18.8 kg (range: $13.4-25.7 \mathrm{~kg}$ ) (ALB-Figure 3a).

## South Atlantic

The recent total annual South Atlantic albacore landings were largely attributed to four fisheries, namely the surface baitboat fleets of South Africa and Namibia, and the longline fleets of Brazil and Chinese Taipei (ALBTable 1; ALB-Figure 2b). The surface fleets are entirely albacore directed and mainly catch juvenile and subadult fish ( 70 cm to 90 cm FL). These surface fisheries operate seasonally, from October to May, when albacore are available in coastal waters. Brazilian longliners target albacore during the first and fourth quarters of the year, when an important concentration of adult fish ( $>90 \mathrm{~cm}$ ) is observed off the northeast coast off Brazil, between $5^{\circ} \mathrm{S}$ and $20^{\circ} \mathrm{S}$, being likely related to favorable environmental conditions for spawning, particularly of sea surface temperature. The longline Chinese Taipei fleet operates over a larger area and throughout the year, and consists of vessels that target albacore and vessels that take albacore as by-catch, in bigeye directed fishing operations. On average, the longline vessels catch larger albacore ( 60 cm to 120 cm FL) than the surface fleets.

Total reported albacore landings for 2009 were $22,856 \mathrm{t}$ an increase of about $21 \%$ from 2008 catch. The Chinese Taipei catch in 2009 was $8,678 \mathrm{t}$, a decrease of $1,288 \mathrm{t}$ as compared to that of 2008 . This decrease mainly stemmed from a decrease in fishing effort targeting albacore. Chinese Taipei longliners (including boats flagged Belize and St. Vincent \& the Grenadines) stopped fishing for Brazil in 2003, which resulted in albacore only being caught as by-catch in tropical tuna-directed longline fisheries. Albacore is only caught as by-catch in Brazilian tropical tuna-directed longline and baitboat fisheries. In 2009, the catch of the Brazilian fishery was 202 t , showing a decrease of about $50 \%$ compared to 2008 . The average catch of about $4,287 \mathrm{t}$ during the period 2000-2003 was obtained by the longline Brazilian fleet when albacore was a target species. In 2009, Uruguay reported 685 t , which represent an extremely high increase from previous reported years.

In 2009, South Africa estimated the total annual catch taken by the baitboat fleet was 5043 t , which represented an increase of about $45 \%$ from 2008. In addition, in 2009 the Namibian total reported catch by the baitboat fleet was $4,936 \mathrm{t}$, an increase of two and a half fold from 2008. Japan takes albacore as by-catch using longline gear. In 2009, the Japanese longline catch was 949 t , a decrease from 2008. The relatively large increase from 238 t in 2007 was due to an increase in fishing effort in the waters off southern Africa (20-40 ${ }^{\circ}$ ). Recent CPUEs from the Chinese Taipei longline fishery in 2008 showed the same level as in 2007 (SCRS/2009/107).

The trend in mean weight for all surface fleets (baitboat and other surface fleets) from the 1975 to 2005 period is shown in ALB-Figure 3b. From 1981 onwards a stable trend is identified with an average of 13.4 kg and maximum and minimum weight of 17.6 kg and 11 kg , respectively. While the trend in mean weight for longline fisheries showed an increase after 1996.

## Mediterranean

In 2009, the reported landings were $4,021 \mathrm{t}$, an increase from 2,970 t taken in 2008 (ALB-Table 1 and ALBFigure 2c). The majority of the catch came from longline fisheries.

## ALB-3. State of stocks

A thorough revision of North Atlantic Task I and Task II data was conducted and a more robust method for catch-at-size analyses was implemented for the 2009 assessment session similar to that used in the 2007 assessment. In addition, catch rate analyses were improved and updated with new information for the northern albacore fisheries and substantial effort was undertaken to implement assessment methods which do not assume that catch-at-age is perfectly known. The analyses were also conducted to incorporate longer time-series of catch, effort and size information into the assessment to guide the evaluation. The approach provided the opportunity to evaluate a range of hypothesis about how the fisheries operated over time and their impact on the population. The results of these efforts are reflected in the following summaries of stock status that analyzed data through 2007.

## North Atlantic

The CPUE trends for the various surface fleets, based upon the most recent available 2007 data showed somewhat different patterns from each other. This was also the case for the different longline fleets (ALBFigure 4). The Spanish age two troll CPUE series showed evidence of a relatively strong 2003 year class entering the fishery. For the Spanish age three troll CPUE series, the age signal is not as strong, leading to uncertainty about the possibility of a good year class. For the longline fleets, the general trend in CPUE indices is a decline over time, with varying rates. Given the variability associated with these catch rate estimates, definitive conclusions about recent trends could not be reached just by examining the CPUE trends alone which represent different parts of the population.

The data sets used for the analyses from 1930 to 2007 were compiled during the July 2009 stock assessment meeting. The data was classified into 10 fisheries units using the same definitions as those used in the 2007 stock assessment. The basic input data, catch, effort and catch-at-size were revised due to updates in the ICCAT Task I (Table 1) and Task II database. Model specification for the base case was identical to the 2007 assessment and described in detail in document SCRS/2009/108, however the model was run using the latest version of the software. Different hypothesis on the dynamics of the northern albacore stock were tested and those with clearly unrealistic outputs were discarded.

Based on the present assessment which considers catch and effort since the 1930s and size frequency since 1959, the view of the northern albacore resource status is that spawning stock size has declined and in 2007 was about one third of the peak levels estimated for the late-1940s. Estimates of recruitment to the fishery, although variable, have shown generally higher levels in the 1960s and earlier periods with a declining trend thereafter until 2007. The most recent recruitment is estimated to be the lowest for all the years of the evaluation although the magnitude of this year-class is highly uncertain in the latest year (ALB-Figure 5). The 2009 current assessment indicated that the stock has remained below $\mathrm{B}_{\mathrm{MSY}}$ (current $\mathrm{SSB}_{2007}$ is approximately $62 \%$ of SSB at MSY) (ALB-Figure 5) since the late 1960. Corresponding fishing mortality rates have been above $\mathrm{F}_{\text {MSY }}$ (current ratio $\mathrm{F}_{2007} / \mathrm{F}_{\mathrm{MSY}}$ is 1.05 which is only slightly higher than $\mathrm{F}_{\mathrm{MSY}}$. (ALB-Figure 6).

The trajectory of fishing mortality and spawning stock biomass relative to MSY reference points, from the assessment model is shown in ALB-Figure 6. As the majority of the time series is in the top left quadrant ( $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}>1$ and, $\mathrm{SSB} / \mathrm{SSB}_{\text {MSY }}<1$ ) this could indicate the northern albacore stock has been overfished $\left(\mathrm{SSB} / \mathrm{SSB}_{\text {MSY }}<1\right)$ since the mid-1980s. Uncertainty around the estimates of current $\mathrm{F}_{2007} / \mathrm{F}_{\text {MSY }}$ and $\mathrm{SSB}_{2007} / \mathrm{SSB}_{\mathrm{MSY}}$ is shown in (ALB-Figure 7).

## South Atlantic

In 2003, the Committee assessed the status of the southern Atlantic albacore stock using the same specifications as were used in 2000, but with updated data. Because of the detailed review, revisions, and updates of the data since that time, the Committee was able to incorporate additional information into the model used for assessing the southern Albacore stock and incorporated an assessment methodology that more objectively brought information about fishery selectivity into the evaluation.

The southern CPUE trends, mainly based on an updated longline standardized CPUE series up to 2007 which harvest mostly mature albacore, showed a strong declining trend in the early part of the time series, and less steep decline over the past decade; while those from the surface fishery, harvesting mostly juvenile albacore, are more recent and show no apparent trend (ALB-Figure 8).

Based on the 2007 assessment which considers catch, size and effort since the 1950s, our view of the southern albacore resource status stock is that the spawning stock has declined to about $25 \%$ of its unfished level in 2005 (ALB-Figure 9). The Committee concluded that it is likely that the stock was below the maximum sustainable yield (MSY) level as it was estimated to about $90 \%$ of $B_{\text {MSY }}$ in 2005, while the 2005 fishing mortality rate was about $60 \%$ of $\mathrm{F}_{\text {MSY }}$. MSY was estimated to be around $33,300 \mathrm{t}$, whereas the replacement yield averaged over the last 10 years, is approximately $29,000 \mathrm{t}$.

Distribution of the pairs of current 2005 status of catch and fishing mortality ratios estimated from the production model are displayed to show the uncertainty around the estimates (ALB-Figure 10).

## Mediterranean

In 2010, Mediterranean albacore Task I and Task II data were reviewed. As a result, deficiencies and a lack of information were identified on statistics from major fleets. The detailed information is presented in report SCI032. In order to asses the status of this stock, the CPCs should provide revised and complete data for this purpose.

## ALB-4. Outlook

## North Atlantic

Using the reference points calculated by the current base case assessment model done in 2009, projections (SCRS/2009/164) indicate that constant catches above $28,000 \mathrm{t}$ will not result in stock rebuilding to Convention standards by 2020 (ALB-Figure 11). In 2008 and 2009 catches were lower than 28,000 t.

## South Atlantic

The assessment indicates that the spawning stock will increase from the levels estimated in 2005 over the next few years, assuming catches in 2006 and 2007 remain about the 2005 level, which is below the estimated replacement yield of about 29,000 t . Since then catches had been lower than 29,000 t (ALB-Figure 9)

## ALB-5. Effects of current regulations

## North Atlantic

In 2007, the Commission established a new TAC for 2008 and 2009 of 30,200 t [Rec. 07-02], but included several provisions that allow the catch to exceed this level.

Furthermore, a 1998 recommendation that limits fishing capacity to the average of 1993-1995, remains in force.
The Committee noted that the reported catches of $20,449 \mathrm{t}$ in 2008 were below the recommended TAC and in 2009 the total catch of $15,364 \mathrm{t}$ was again lower than the TAC (ALB-Table 1).

## South Atlantic

In 2007 the Commission established a new TAC from 2008 to 2011 of 29,900 t [Rec. 07-03]. The Committee noted that reported catches in 2008 and 2009 were well below the TAC (ALB-Table 1).

## Mediterranean

There are no ICCAT regulations directly aimed at managing the Mediterranean albacore stock.

## ALB-6. Management recommendations

## North Atlantic

In 2007, the Commission implemented [Rec. 07-02], intended to reduce the TAC to 30,200 t in 2008 and 2009 and allow the rebuilding of the northern albacore stock from the overfished condition. However, it was reiterated that the fishing opportunities provided in [Rec. 07-02] allow the potential catch to exceed the TAC (ALB-Figure 2a). In view of the 2009 assessment, in order to achieve the Commission management objective by 2020, a level of catch of no more than $28,000 \mathrm{t}$ will be required. The Commission recommended the establishment of a Total Allowable Catch (TAC) of 28,000 t for 2010 and 2011 [Rec. 09-05].

## South Atlantic

In the case of the southern stock, the present TAC is $29,900 \mathrm{t}$. Recent catches were below the TAC level. The 2007 assessment showed that the southern stock was overfished and model projections indicated that catches, at about the 2006 level ( $24,452 \mathrm{t}$ ), will recover the stock..

The Committee considered that the current management regulations are sufficient for the recovery of the southern stock. In 2007, the Commission recommended [Rec. 07-03] adopting a catch limit of 29,900 t (the lowest estimate of MSY) until 2011. The Commission recommended updating the southern albacore stock assessment in 2011 [Rec. 07-03].

ALB-Figure 4. Standardized catch rate indices used in the 2009 northern albacore stock assessment from the surface fisheries (upper panel), which take mostly juvenile fish, and from the longline fisheries (lower panel), which take mostly adult fish.

ALB-Figure 5. Estimates of northern Atlantic albacore recruitment (age 1) and spawning stock size from 19302007 from Multifan-CL model assesment. Uncertainty in the estimates has not been characterized, but the uncertainty in recent recruitment levels is considered to be higher than in the past.

ALB-Figure 6. Stock status of northern albacore, estimated with Multifan-CL. Top: Relative biomass $\left(\mathrm{SSB} / \mathrm{SSB}_{\mathrm{MSY}}\right)$ and relative fishing mortality ( $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ ) trajectories over time. Bottom: joint trajectories of SSB/SSB MSY and $F / \mathrm{F}_{\text {MSY }}$. The red X cross in the lower panel represents the stock status in 2007.

ALB-Figure 7. Uncertainty in current stock status for northern albacore, as estimated from the Multifan base case model. The X represents the current (2007) estimates of fishing mortality and spawning biomass ratios, and the scatter of points depicts uncertainty in that estimate.

ALB-Figure 8. Standardized catch rates indices used in the 2007 southern albacore stock assessment from the longline fisheries (upper panel), which take mostly mature fish, and from the surface fisheries (lower panel), which take mostly juvenile fish.

ALB-Figure 9. The upper plate indicates southern albacore spawning biomass over time, projections with a constant catch of $25,000 \mathrm{t}$ over the next years and the reference SSB $_{\text {MSY }}$ level with $80 \%$ confidence bounds. The lower plate indicates catch relative to replacement yield vs. current biomass relative to the biomass at MSY for the period 1970-2005. The circles are the current state of the stock for all the sensitivity runs.

ALB-Figure 10. The distribution of stock status determination for South Atlantic albacore in 2005 indicating the uncertainty in this evaluation.

ALB-Figure 11. Estimated projections of relative SSB (SSB/SSB MSY ) for different scenarios of constant catch ( $20,000 \mathrm{t}-36,000 \mathrm{t}$ ) assuming average recent year-class strengths for the North Atlantic albacore stock. Projections assumed a catch of $30,200 \mathrm{t}$ in 2008 and 2009.

### 8.5 BFT - ATLANTIC BLUEFIN TUNA

The SCRS conducted a comprehensive assessment of bluefin tuna in the Atlantic and the Mediterranean in 2010. In the assessment, the available data included catch, effort and size statistics through 2009. As previously discussed, there are considerable data limitations for the eastern stock up to 2007. While data reporting for the eastern and Mediterranean fisheries has substantially improved since 2008 and some historical statistical data have been recovered, most of the data limitations that have plagued previous assessments remain and new approaches will be required in order to improve the scientific advice the Committee can offer.

The Atlantic-wide Bluefin Tuna Research Program (GBYP) research plan outlined the research necessary for improving the scientific advice that the Committee provides to the Commission. This plan was presented to and approved by the Commission and the GBYP was started in 2010. The Committee continues to strongly and unanimously support the GBYP, and welcomes the Commission's continued commitment to the Program. In the absence of such a significant and sustained effort, it remains highly unlikely that the Committee will improve its scientific diagnosis and management advice in the foreseeable future.

## BFT-1. Biology

Atlantic bluefin tuna (BFT) mainly live in the pelagic ecosystem of the entire North Atlantic and its adjacent seas, primarily the Mediterranean Sea. Bluefin tuna has a wide geographical distribution and is one of the only large pelagic fish living permanently in temperate Atlantic waters (BFT-Figure 1). Archival tagging and tracking information confirmed that bluefin tuna can sustain cold as well as warm temperatures while maintaining a stable internal body temperature. Until recently, it was assumed that bluefin tuna preferentially occupy the surface and subsurface waters of the coastal and open-sea areas, but archival tagging and ultrasonic telemetry data indicate that bluefin tuna frequently dive to depths of 500 m to $1,000 \mathrm{~m}$. Bluefin tuna is also a highly migratory species that seems to display a homing behavior and spawning site fidelity in both the Mediterranean Sea and Gulf of Mexico, which constitute the two main spawning areas being clearly identified today. Less is known about feeding migrations within the Mediterranean and the North Atlantic, but results from electronic tagging indicated that bluefin tuna movement patterns vary considerably between individuals, years and areas. The appearance and disappearance of important past fisheries further suggest that important changes in the spatial dynamics of bluefin tuna may also have resulted from interactions between biological factors, environmental variations and fishing. Although the Atlantic bluefin tuna population is managed as two stocks, conventionally separated by the $45^{\circ} \mathrm{W}$ meridian, its population structure remains poorly understood and needs to be further investigated. Recent genetic and microchemistry studies as well as work based on historical fisheries tend to indicate that the bluefin tuna population structure is complex.

Currently, bluefin tuna is assumed to mature at approximately 25 kg (age 4) in the Mediterranean and at approximately 145 kg (age 9) in the Gulf of Mexico. Juvenile and adult bluefin tuna are opportunistic feeders (as are most predators). However, in general, juveniles feed on crustaceans, fish and cephalopods, while adults primarily feed on fish such as herring, anchovy, sand lance, sardine, sprat, bluefish and mackerel. Juvenile growth is rapid for a teleost fish (about $30 \mathrm{~cm} /$ year), but slower than other tuna and billfish species. Fish born in June attain a length of about $30-40 \mathrm{~cm}$ long and a weight of about 1 kg by October. After one year, fish reach about 4 kg and 60 cm long. Growth in length tends to be lower for adults than juveniles, but growth in weight increases. At 10 years old, a bluefin tuna is about 200 cm and 170 kg and reaches about 270 cm and 400 kg at 20 years. Bluefin tuna is a long lived species, with a lifespan of about 40 years, as indicated by recent studies from radiocarbon deposition.

The information on natal origin derived from otolith microchemistry received by the SCRS, which was based on limited samples, indicated that the contribution of eastern origin fish to the western fisheries decreases with size (i.e. up to $62 \%$ for fish in the 69-119 cm size class, but negligible for fish greater than 250 cm ). In contrast, other western fisheries supported by the largest size classes had minimal or no eastern component in the catch. However, there remains considerable uncertainty and therefore additional samples are needed to improve our understanding of the relative contribution of the two stocks to the different fisheries over time. An issue that can hardly be resolved without better understanding of Atlantic bluefin tuna population structure.

In 2009, the SCRS received considerable new information on maturity, growth, and the spatial dynamics of Atlantic and Mediterranean bluefin (see SCRS/2009/192). Following key developments are summarized below.

The SCRS had extensive discussions concerning the choice of maturity schedules for both the eastern and western stocks. Uncertainty in age at maturity remained a significant issue for the stock assessment, and obliged
the Group to consider alternative scenarios during their modeling work. Improving current understanding of the maturity schedules for bluefin tuna should be a priority area for research within the GBYP and other collaborative research programs with the SCRS.

The SCRS implemented a new growth curve for western stock that was derived from advanced analytical techniques. The adoption of the new growth curve that is nearly identical to that for the eastern stock has resulted in significant changes to some of the benchmark for the western stock and consequently management advice. For the Eastern Atlantic and Mediterranean stock, new information indicated that for farming operations, when applying the weight gain rates adopted by SCRS in 2009, the back calculated fish weights at initial capture seemed to show unrealistic size distributions, in that more fish of a smaller size are calculated as having been caught than would be expected given existing controls.

The SCRS also received several contributions related to electronic tagging within the Eastern Atlantic and Mediterranean stock. While most of the new studies are reporting work in progress, the new information appears to indicate a greater level of complexity in the migratory patterns of the eastern fish than was previously understood, as a significant fraction of the eastern fish (juveniles and spawners) seem to stay within the Mediterranean all year long.

## BFTE-2. Fishery trends and indicators - East Atlantic and Mediterranean

It is very well known that introduction of fattening and farming activities into the Mediterranean in 1997 and good market conditions resulted in rapid changes in the Mediterranean fisheries for bluefin tuna mainly due to increasing purse seine catches. In the last few years, nearly all of the declared Mediterranean bluefin fishery production was exported overseas. Declared catches in the East Atlantic and Mediterranean reached a peak of over 50,000 tin 1996 and, then decreased substantially, stabilizing around TAC levels established by ICCAT for the most recent period (BFT-Table 1 and BFTE-Figure 1). Both the increase and the subsequent decrease in declared production occurred mainly for the Mediterranean (BFTE-Figure 1). For 2006-2009, declared catch was, at the time of the meeting, $30,689 \mathrm{t}, 34,516 \mathrm{t}, 24,057 \mathrm{t}$ and $20,228 \mathrm{t}$ for the East Atlantic and Mediterranean, of which $23,154 \mathrm{t}, 26,479 \mathrm{t}, 16,409 \mathrm{t}$ and $13,527 \mathrm{t}$ were declared for the Mediterranean for those same years (BFT-Table 1).

Information available has demonstrated that catches of bluefin tuna from the East Atlantic and Mediterranean were seriously under-reported between the mid-1990s through 2007. The Committee views this lack of compliance with TAC and underreporting of the catch as having undermined conservation of the stock. The Committee has estimated that realized catches during this period could have been on the order of $50,000 \mathrm{t}$ to $61,000 \mathrm{t}$ per year based on the number of vessels operating in the Mediterranean Sea and their respective catch rates. Estimates for 2008 and 2009 using updated vessel capacity and performance statistics from the various reports submitted to ICCAT under [Rec. 08-05] results in estimates that are significantly lower than the corresponding reported Task I data (see Bluefin tuna Data Preparatory Meeting). Although care is needed considering estimates of catch using these capacity measures, the Committee's interpretation is that a substantial decrease in the catch occurred in the eastern Atlantic and Mediterranean Sea in 2008 and 2009.

Available indicators from small fish fisheries in the Bay of Biscay did not show any clear trend since the mid1970s (BFTE-Figure 2). This result is not particularly surprising because of strong inter-annual variation in year class strength. However, aerial survey results conducted in 2009 indicated a higher abundance or higher concentration of small bluefin in the northwestern Mediterranean than found in surveys conducted in 2000-2003. Indicators from Japanese longliners and Spanish and Moroccan traps targeting large fish (spawners) in the East Atlantic and the Mediterranean Sea displayed a recent increase after a general decline since the mid-1970s (BFTE-Figure 2). Indicators from longliners targeting medium to large fish in the northeast Atlantic were available since 1990 and showed an increasing trend in the recent years (BFTE-Figure 2). This index becomes more valuable since the major part of Japanese catch come from this fishing ground in recent years, while the activities of longliners in the East Atlantic (south of $40^{\circ} \mathrm{N}$ ) and Mediterranean Sea were reduced. Two historical indicators before 1980 in the Bay of Biscay were also available. The Group recognized that the recent compliance to the regulatory measures affect significantly the CPUE values (e.g. Spanish baitboat and Japanese longline indices) through the change of operational pattern and target sizes. Recent tendency in indicators are likely to reflect positive outcomes from recent management measures. However, the Committee found it difficult to derive any clear conclusion from fisheries indicators over such a short period after the implementation of new regulations and in the absence of more precise information about the catch composition, effort and spatial distribution of the purse seine fisheries. Fisheries-independent indicators (scientific surveys) and a large scale
tagging program are needed to provide more reliable stock status indicators. The Committee reaffirmed the importance of pursuing these research elements under the now-funded GBYP.

## BFTE-3. State of the stock

In spite of improvements in the data quantity and quality for the past few years, there remain considerable data limitations for the 2010 assessment of the stock. These included poor temporal and spatial coverage for detailed size and catch-effort statistics for many fisheries, especially in the Mediterranean. Substantial under-reporting of total catches was also evident, especially during 1998-2007. Nevertheless, the Committee assessed the stock in 2010 as requested by the Commission mainly applying the methodologies and hypotheses adopted by the Committee in previous assessments and further tried alternative approaches. The Committee believes that while substantial improvements can be made for in catch and effort statistics into the future, it appears unlikely that such substantial improvements can be made regarding historical fishery performance. Because of this, the Committee believes that assessment methodologies applied in the past must be modified to better accommodate the substantial uncertainties in the historical total catch, catch-at-age and effort data from the main fleets harvesting bluefin. This process has been initiated, but will require at least three years to complete in terms of robustness testing of the methodologies envisioned. The Commission should take this into account in establishing management controls (cf. a TAC for three years). Furthermore, any change in exploitation or management will take several years to have a detectable effect on the biomass because bluefin tuna is a long lived species and our ability to quantify recent management impacts on stock status are limited due to variability in stock status indicators in the most recent years.

The assessment results upon which the Committee's main advice is provided indicated that the spawning stock biomass (SSB) had been mostly declining since the 1970s. The recent SSB tendency has shown signs of increase/stabilization in some runs while it continues to decline for others, depending on the models specifications and data used (see BFT detailed report, BFTE-Figure 3). Trend in fishing mortality (F) displayed a continuous increase over the time period for the younger ages (ages 2-5) while for oldest fish (ages 10+) it had been decreasing during the first 2 decades and then rapidly increased during the 1990s. Fishing mortalities have declined on the oldest fish in recent years, but these for younger (ages 2-5) are more uncertain and display higher variability (BFTE-Figure 3). General trends in F or N were not strongly affected by the historical catches assumptions (i.e. reported versus inflated), except in recent years. These analyses indicated that recent (20072009) SSB is about $57 \%$ of the highest estimated SSB levels (1957-1959). Recent recruitment levels remain very uncertain due to the lack of information about incoming year class strength and high variability in the indicators used to track recruitment and the low recent catches of fish less than the minimum size. The absolute values estimated for F and SSB remained sensitive to the assumptions of the analysis and could lead to a different perception in the whole trend in SSB. However, it is noteworthy that the historical Fs for older fish were consistent between different types of models which made use of different assumptions. For the years 1995-2007, Fs for older fish are also consistent with a shift in targeting towards larger individuals destined for fattening and/or farming.

Estimates of current stock status relative to MSY benchmarks are uncertain, but lead to the conclusion that although the recent Fs have probably declined, these values remain too high and recent SSB too low to be consistent with the Convention objectives. Depending on different assumed levels of resource productivity current F show signs of decline reflecting recent catch reductions, but remained larger than that which would result in MSY and SSB remained most likely to be about $35 \%$ (from $19 \%$ to $51 \%$ depending on the recruitment levels) than the level needed to support MSY (BFTE-Figure 4).

## BFTE- 4. Outlook

During the last decade, there has been an overall shift in targeting towards large bluefin tuna, mostly in the Mediterranean. As the majority of these fish are destined for fattening and/or farming operations, it is crucial to get precise information about the total catch, the size composition, the area and flag of capture. Progress has been made over the last years, but current information that consists in individual weight after fattening remain too uncertain to be used within stock assessment models. Therefore, real size samples at time of the catch are still required and the SCRS strongly encourages the use of dual camera system or other technology that could provide sizes of fish entering into cages.

The shift towards larger fish should result in improved yield-per-recruit levels in the long-term if F were reduced to $\mathrm{F}_{0.1}$. However, such changes would take several years to translate into gains in yield due to the longevity of the species. Realization of higher long-term yields would further depend on future recruitment levels.

Even considering uncertainties in the analyses, the outlook derived from the 2010 assessment has improved in comparison to previous assessments, as F for older fish seem to have significantly declined during the last two years. However, estimates in the last years are known to be more uncertain and this decline (as the Fs for younger ages which remains more variable) needs to be confirmed in future analyses. Nonetheless, $\mathrm{F}_{2009}$ still remains largely above the reference target $\mathrm{F}_{0.1}$ (a reference point more robust to uncertainties than $\mathrm{F}_{\mathrm{MAX}}$, as used in the past) while SSB is only about $35 \%$ of the biomass that is expected under a MSY strategy (BFTE-Figure 4).

The Committee also evaluated the potential effects of [Rec. 09-06]. Acknowledging that there is insufficient scientific information to determine precisely the productivity of the stock (i.e. the steepness of the stockrecruitment relationship), the Committee agreed to perform the projections with three recruitment levels while taking into account for year-to-year variations. These levels correspond to the 'low' and 'high' scenarios as defined in the 2008 assessment plus a 'Medium' scenario that corresponds to the geometric mean of the recruitment over the 1950-2006 years. For the projections, the group investigated 24 scenarios (see bluefin tuna detailed report) which were assessed against the range of constant catch from 0 to $20,000 \mathrm{t}$. The results indicated that the stock is increasing in all the cases, but the probability to achieve $\operatorname{SSB}_{\mathrm{F} 0.1}$ (i.e. the equilibrium SSB resulting in fishing at $\mathrm{F}_{0.1}$ ) by the end of 2022 depend on the scenarios (run 13 leads to slower rebuilding than run 15 while the recruitment levels affect both the speed of rebuilding and the level of overfishing, see BFT detailed report). Overall, the SSB would be equal or greater than $\mathrm{SSB}_{\mathrm{F} 0.1}$ by the end of 2022 for a catch $=0$ to $13,500 \mathrm{t}$, but not when the catch is greater than $14,000 \mathrm{t}$ (BFTE-Table 2, BFTE-Figure 6). It is finally worth noting that a $\mathrm{F}_{0.1}$ strategy starting in 2011 would not allow the rebuilding of the stock to $\mathrm{SSB}_{\mathrm{F} 0.1}$ by 2022, but later on.

Projections are known to be impaired by various sources of uncertainties that have not yet been quantified. Although the situation has improved regarding recent catch, there are still uncertainties about stock status in 2009, population structure and migratory rates as well as a lack of knowledge about the level of IUU catch and key modeling parameters on BFT productivity. Acknowledging these limitations, the overall evaluation of [Rec. 09-06] indicated that the rebuilding of BFTE at $\mathrm{SSB}_{\mathrm{F} 0.1}$ level with a probability of at least $60 \%$ could be achieved by 2019 with zero catch and by 2022 with catch equal to current TAC (i.e. 13,500 t). However, this $60 \%$ probability level is unlikely to be attained by the end of 2022 with a catch greater than $14,000 \mathrm{t}$. Finally, it should be noted that the incorporation of additional uncertainties into the overall analysis could change the estimates of rebuilding probability.

## BFTE-5. Effect of current regulations

Catch limits have been in place for the eastern Atlantic and Mediterranean management unit since 1998. In 2002, the Commission fixed the Total Allowable Catch (TAC) for the East Atlantic and Mediterranean bluefin tuna at $32,000 \mathrm{t}$ for the years 2003 to 2006 [Rec. 02-08] and at 29,500 t and 28,500 t for 2007 and 2008, respectively [Rec. 06-05]. Subsequently, [Rec. 08-05] established TACs for 2009, 2010, and 2011 at 22,000 t, 19,950 t, and $18,500 \mathrm{t}$, respectively. However, the 2010 TAC was revised to $13,500 \mathrm{t}$ by [Rec. 09-06] which also established a framework to set future (2011 and beyond) TAC at levels sufficient to rebuild the stock to $\mathrm{B}_{\text {MSY }}$ by 2022 with at least 60\% probability.

The reported catches for 2003, 2004 and 2006 were about TAC levels, but those for 2005 ( $35,845 \mathrm{t}$ ) and 2007 ( $34,516 \mathrm{t}$ ) were notably higher than TAC. However, the Committee strongly believes, based on the knowledge of the fisheries and trade statistics, that substantial under-reporting was occurring and that actual catches up to 2007 were well above TAC. The SCRS estimates since the late-1990s, catches were close to the levels reported in the mid-1990s, but for 2007, the estimates were higher i.e. about $61,000 \mathrm{t}$ in 2007 for both the East Atlantic and Mediterranean Sea. As noted, reported catch levels for 2008 (24,057 t) and 2009 (20,228 t) appear to largely reflect the removals from the stock when comparing estimates of catch using vessel capacity measures, although the utility of this method has diminished for estimating catch. The reported catches for 2008 and 2009 are 10,000 t to $15,000 \mathrm{t}$ lower than the 2003-2007 reported catches (BFTE-Table 1, BFTE-Figure 1). Although care is needed considering estimates of catch using capacity measures, the Committee's interpretation is that a substantial decrease in the catch occurred in the Eastern Atlantic and Mediterranean Sea through implementation of the rebuilding plan and through monitoring and enforcement controls. While current controls appear sufficient to constrain the fleet to harvests at or below TAC, should it not be the case, the Committee remains concerned
about substantial excess capacity remains which could harvest catch volumes well in excess of the rebuilding strategy adopted by the Commission.

Recent analyses of the size and age composition of reported catches show important changes in selectivity patterns over the last three years for several fleets operating in the Mediterranean Sea or the East Atlantic. This partly results from the enforcement of minimum size regulations under [Rec. 06-05] which led to much lower reported catch of small fish and subsequently a steep increase in the annual mean-weight in the catches since 2007 (BFTE-Figure 5). Additionally, higher abundance or higher concentration of small bluefin tuna in the northwest Mediterranean detected from aerial surveys could also reflect positive outcomes from increase minimum size regulation.

While several fishery indicators have shown some positive tendency in the most recent fishing seasons, the available catch effort statistics are not yet sufficient to permit the Committee to quantify the extent of impact of the recent regulations on the overall stock with precision. The Committee's view is that it will take additional years under constrained fishing before to measure it more precisely.

## BFTE-6. Management Recommendations

In [Rec. 09-06] the Commission established a total allowable catch for eastern Atlantic and Mediterranean bluefin tuna at 13,500 $t$ in 2010. Additionally, in [Rec. 09-06] the Commission required that the SCRS provide the scientific basis for the Commission to establish a three-year recovery plan for 2011-2013 with the goal of achieving $\mathrm{B}_{\text {MSY }}$ through 2022 with at least $60 \%$ of probability.

A Kobe II strategy matrix reflecting recovery scenarios of eastern Atlantic and Mediterranean bluefin tuna in accordance with the multiannual recovery plan is given in BFTE-Table 1 and BFTE-Figure 6.

The implementation of recent regulations through [Rec. 09-06, and previous recommendations] has clearly resulted in reductions in catch and fishing mortality rates. But, since the fishery is currently adapting to these new management measures, the Committee is unable to fully understand the implications of the measures on the stock. The Commission might consider a probability of rebuilding standard different from that envisaged in [Rec. 09-06] considering the unquantified uncertainties. However, the Committee notes that maintaining catches at the current TAC ( $13,500 \mathrm{t}$ ) or less under the current management scheme, for 2011-2013, will likely allow the stock to increase during that period and is consistent with the goal of achieving $\mathrm{F}_{\text {MSY }}$ and $\mathrm{B}_{\text {MSY }}$ through 2022 with at least $60 \%$ of probability, given the quantified uncertainties.

## EAST ATLANTIC AND MEDITERRANEAN BLUEFIN TUNA SUMMARY

Current (2009) Yield ${ }^{1}$ Reported: 19,701 t SCRS estimate: 18,308 t

Short-term Sustainable Yield according to Rec.[09.06]

Long-term potential yield ${ }^{2}$ about 50,000 t
$\mathrm{SSB}_{2009} / \mathrm{SSB}_{\mathrm{F} 0.1}\left(\mathrm{SSB}_{2009} / \mathrm{SSB}_{\mathrm{FMAX}}\right)^{3}$
Medium recruitment (1950-2006)
Low recruitment (1970s)
High recruitment (1990s)
$\mathrm{F}_{2009} / \mathrm{F}_{0.1}\left(\mathrm{~F}_{2009} / \mathrm{F}_{\mathrm{MAX}}\right)^{4}$
Reported and Inflated catches
TAC (2009-2010)
$13,500 \mathrm{t}$ or less
0.35 (0.62)
0.51 (0.88)
0.19 (0.33)
-19,950 t-13,500 t
${ }^{1}$ Corresponds to the reported catches on the October 07, 2010. SCRS estimate is based on updated vessel capacity and vessel catch rates information (see BFT data prep. Report). Note that the 2009 catch estimate used in the 2010 stock assessment was $20,228 \mathrm{t}$ due to estimations of missing reports at the date of the meeting (see BFT-Table 1).
${ }^{2}$ Approximated as the average of long-term yield at $\mathrm{F}_{0.1}$ that was calculated over a broad range of scenarios including contrasting recruitment levels and different selectivity patterns (estimates from these scenarios ranged between 29,000 t and $91,000 \mathrm{t}$ ).
${ }^{3}$ The Committee decided, on the basis of current published literature, to adopt $F_{0.1}$ as the proxy for $F_{\text {MSY }}$ instead of $F_{\text {MAX }}$. $\mathrm{F}_{0.1}$ has been indeed shown to be more robust to observation errors and uncertainty about the true dynamics of the stock than $\mathrm{F}_{\mathrm{mAX}}$. However, references to
$\mathrm{F}_{\text {MAX }}$ are also given in parentheses for comparison purposes.
${ }^{4}$ The recruitment levels do not impact $\mathrm{F}_{2009} / \mathrm{F}_{0.1}$ or $\mathrm{F}_{2009} / \mathrm{F}_{\text {MAX }}$.

## BLUEFIN TUNA - WEST

## BFTW-2. Fishery indicators

The total catch for the West Atlantic peaked at $18,671 \mathrm{t}$ in 1964, mostly due to the Japanese longline fishery for large fish off Brazil and the U.S. purse seine fishery for juvenile fish (BFT-Table 1, BFTW-Figure1). Catches dropped sharply thereafter with the collapse of the bluefin tuna by-catch longline fishery off Brazil in 1967 and decline in purse seine catches, but increased again to average over $5,000 \mathrm{t}$ in the 1970 s due to the expansion of the Japanese longline fleet into the northwest Atlantic and Gulf of Mexico and an increase in purse seine effort targeting larger fish for the sashimi market. The total catch for the West Atlantic including discards has generally been relatively stable since 1982 due to the imposition of quotas. However, since a total catch level of 3,319 tin 2002(the highest since 1981, with all three major fishing nations indicating higher catches), total catch in the West Atlantic declined steadily to a low of $1,638 \mathrm{t}$ in 2007 and then increased in 2008 to 2,000 t. and slightly decreased in 2009 to 1,935 t (BFTW-Figure 1). The decline through 2007 was primarily due to considerable reductions in catch levels for U.S. fisheries. Since 2002, the Canadian annual catches have been relatively stable at about 500-600 t ( 733 t in 2006); the 2006 catch was the highest recorded since 1977. The 2009 Canadian catch was 530 t . Japanese catches have generally fluctuated between 300-500 t, with the exception of 2003 ( 57 t ), which was low for regulatory reasons. However, Japanese landings for 2009 corresponded to only 162 t .

The average weight of BFT taken by the combined fisheries in the West Atlantic were historically low during the 1960s and 1970s (BFTW-Figure 2), for instance showing an average weight of only 33 kg during the 19651975 period. However, since 1980 they have been showing a quite stable trend and at a quite high average weight of 93 kg .

The overall number of Japanese vessels engaged in bluefin fishing has declined from more than 100 vessels to currently less than 10 vessels in the West Atlantic. After reaching 2,014 t in 2002 (the highest level since 1979), the catches (landings and discards) of U.S. vessels fishing in the northwest Atlantic (including the Gulf of Mexico) declined precipitously during 2003-2007. The United States did not catch its quota in 2004-2008 with catches of $1,066,848,615,858$ and 922 t , respectively. However, in 2009 the United States fully realized its base quota with total catches (landings including dead discards) of 1,228 t .

The indices of abundance used in this year's assessment were updated through 2009 (BFTW-Figure 3). The catch rates of juvenile bluefin tuna in the U.S. rod and reel fishery fluctuate with little apparent long-term trend, but exhibit a pattern that is consistent with the strong year-class estimated for 2003. The catch rates of adults in the U.S. rod and reel fishery continue to remain low, increasing only slightly in 2008 and decreasing once again in 2009. The catch rates of the Japanese longline fishery increased markedly in 2007, decreased in 2008 back to the levels observed in 2005 and 2006 and it increased once again in 2009. The catch rates from the U.S. Gulf of Mexico longline fishery continue to show a gradual increasing trend, whereas the Gulf of Mexico larval survey continues to fluctuate around the low levels observed since the 1980s. The catch rates in the Gulf of St. Lawrence have increased rapidly since 2004 and the catch rates in is the highest in the time series. The catch rates in southwest Nova Scotia have continued to follow a slightly increasing trend since 2000, with catch rates in 2009 being amongst the highest since the early 1990s.

## BFTW-3. State of the stock

A new assessment was conducted this year, including information through 2009. The most influential change since the 2008 assessment was the use of a new growth curve that assigns fish above 120 cm to older ages than did the previous growth curve. As a result, the base model estimates lower fishing mortality rates and higher biomasses for spawners, but also less potential in terms of the maximum sustainable yield. The trends estimated during the 2010 assessment are consistent with previous analyses in that spawning stock biomass (SSB) declined steadily from 1970 to 1992 and has since fluctuated between $21 \%$ and $29 \%$ of the 1970 level (BFTW-Figure 4). In recent years, however, there appears to have been a gradual increase in SSB from the low of $21 \%$ in 2003 to an estimated $29 \%$ in 2009. The stock has experienced different levels of fishing mortality ( F ) over time, depending on the size of fish targeted by various fleets (BFTW-Figure 4). Fishing mortality on spawners (ages 9 and older) declined markedly after 2003.

Estimates of recruitment were very high in the early 1970s (BFTW-Figure 4), and additional analyses involving longer catch and index series suggest that recruitment was also high during the 1960s. Since 1977, recruitment has varied from year to year without trend with the exception of a strong year-class in 2003. The 2003 year-class
is estimated to be the largest since 1974, but not quite as large as those prior to 1974. The 2003 year class is expected to begin to contribute to an increase in spawning biomass after several years. The Committee expressed concern that the year-class estimates subsequent to 2003, while less reliable, are the lowest on record.

A key factor in estimating MSY-related benchmarks is the highest level of recruitment that can be achieved in the long term. Assuming that average recruitment cannot reach the high levels from the early 1970s, recent F (2006-2008) is $70 \%$ of the MSY level and $\mathrm{SSB}_{2009}$ is about $10 \%$ higher than the MSY level (BFTW-Figure 5). Estimates of stock status are more pessimistic if a high recruitment scenario is considered ( $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}=1.9$, $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}=0.15$ ).

One important factor in the recent decline of fishing mortality on large bluefin is that the TAC had not been taken during this time period until 2009, due primarily to a shortfall by the United States fisheries (until 2009). Two plausible explanations for the shortfall were put forward previously by the Committee: (1) that availability of fish to the United States fishery has been abnormally low, and/or (2) the overall size of the population in the Western Atlantic declined substantially from the level of recent years. While there is no overwhelming evidence to favor either explanation over the other, the base case assessment implicitly favors the first hypothesis (regional changes in availability) by virtue of the estimated increase in SSB. The decrease indicated by the U.S. catch rate of large fish is matched by an increase in several other large fish indices (BFTW-Figure 3). Nevertheless, the Committee notes that there remains substantial uncertainty on this issue and more research needs to be done.

The SCRS cautions that the conclusions of this assessment do not capture the full degree of uncertainty in the assessments and projections. An important factor contributing to uncertainty is mixing between fish of eastern and western origin. Limited analyses were conducted of the two stocks with mixing in 2008, but little new information was available in 2010. Based on earlier work, the estimates of stock status can be expected to vary considerably depending on the type of data used to estimate mixing (conventional tagging or isotope signature samples) and modeling assumptions made. More research needs to be done before mixing models can be used operationally for management advice. Another important source of uncertainty is recruitment, both in terms of recent levels (which are estimated with low precision in the assessment), and potential future levels (the "low" vs. "high" recruitment hypotheses which affect management benchmarks). Improved knowledge of maturity at age will also affect the perception of changes in stock size. Finally, the lack of representative samples of otoliths requires determining the catch at age from length samples, which is imprecise for larger bluefin tuna.

## BFTW-4. Outlook

A medium-term (10-year) outlook evaluation of changes in spawning stock size and yield over the remaining rebuilding period under various management options was conducted. Future recruitment was assumed to fluctuate around two alternative scenarios: (i) average levels observed for 1976-2006 (85,000 recruits, the low recruitment scenario) and (ii) levels that increase as the stock rebuilds (MSY level of 270,000 recruits, the high recruitment scenario). The Committee has no strong evidence to favor either scenario over the other and notes that both are reasonable (but not extreme) lower and upper bounds on rebuilding potential.

The outlook for bluefin tuna in the West Atlantic with the low recruitment scenario (BFTW-Figure 6) is more optimistic with respect to current stock status than that from the 2008 assessment (owing to the use of improved information on the growth of bluefin tuna). A total catch of $2,500 \mathrm{t}$ is predicted to have at least a $50 \%$ chance of achieving the convention objectives of preventing overfishing and maintaining the stock above the MSY level. The outlook under the high recruitment scenario (BFTW-Figure 6) is more pessimistic than the low recruitment scenario since the rebuilding target would be higher; a total catch of less than $1,250 \mathrm{t}$ is predicted to maintain F below $\mathrm{F}_{\text {MSY }}$, but the stock would not be expected to rebuild by 2019 even with no fishing.

BFTW-Table 1 summarizes the estimated chance that various constant catch policies will allow rebuilding under the high and low recruitment scenarios for the base-case. The low recruitment scenario suggests the stock is above the MSY level with greater than $60 \%$ probability and catches of $2,500 \mathrm{t}$ or lower will maintain it above the MSY level. If the high recruitment scenario is correct, then the western stock will not rebuild by 2019 even with no catch, although catches of $1,100 \mathrm{t}$ or less are predicted to have a $60 \%$ chance to immediately end overfishing and initiate rebuilding.

The Committee notes that considerable uncertainties remain for the outlook of the western stock, including the effects of mixing and management measures on the eastern stock

## BFTW-5. Effects of current regulations

The Committee previously noted that Recommendation 06-06 was expected to result in a rebuilding of the stock towards the convention objective, but also noted that there has not yet been enough time to detect with confidence the population response to the measure. This statement is also true for Recommendation 08-04, which was implemented in 2009. Some of the available fishery indicators (BFTW-Figure 3) as well as the current assessment suggest the spawning biomass of western bluefin tuna may be slowly rebuilding.

## BFTW-6. Management recommendations

In 1998, the Commission initiated a 20-year rebuilding plan designed to achieve $\mathrm{B}_{\text {MSY }}$ with at least $50 \%$ probability. In response to recent assessments, in 2008 the Commission recommended a total allowable catch (TAC) of 1,900 $t$ in 2009 and 1,800 $t$ in 2010 [Rec. 08-04].

The current (2010) assessment indicates similar historical trends in abundance as in previous assessments. The strong 2003 year class has contributed to stock productivity such that biomass has been increasing in recent years.

Future stock productivity, as with prior assessments, is based upon two hypotheses about future recruitment: a 'high recruitment scenario" in which future recruitment has the potential to achieve levels that occurred in the early 1970's and a "low recruitment scenario" in which future recruitment is expected to remain near present levels. Results in previous assessments have shown that long term implications of future biomass are different between the two hypotheses and this research question remains unresolved. However, the current (2010) assessment is also based on new information on western bluefin growth rates that has modified the Committee's perception of the ages at which spawning and maturity occur. Maturity schedules remain very uncertain, and, thus, the application of the new information in the current (2010) assessment accentuates the differences between the two recruitment hypotheses.

Probabilities of achieving $\mathrm{B}_{\text {MSY }}$ within the Commission rebuilding period were projected for alternative catch levels (BFTW-Table 1, BFTW-Figure 7). The "low recruitment scenario" suggests that biomass is currently sufficient to produce MSY, whereas the "high recruitment scenario" suggests that $\mathrm{B}_{\text {MSY }}$ has a very low probability of being achieved within the rebuilding period. Despite this large uncertainty about the long term future productivity of the stock, under either recruitment scenario current catches ( $1,800 \mathrm{t}$ ) should allow the biomass to continue to increase. Also, catches in excess of $2,500 \mathrm{t}$ will prevent the possibility of the 2003 year class elevating the productivity potential of the stock in the future.

The SCRS notes that the 2010 assessment is the first time that this strong 2003 year-class has been clearly demonstrated, likely as a result of age assignment refinements resulting from the growth curve and additional years of data; more observations from the fishery are required to confirm its relative strength. A further concern is that subsequent year-classes, although even less well estimated, are the lowest observed values in the time series. The Commission may wish to protect the 2003 year class until it reaches maturity and can contribute to spawning. Maintaining catch at current levels ( $1,800 \mathrm{t}$ ) may offer some protection.

As noted previously by the Committee, both the productivity of western Atlantic bluefin and western Atlantic bluefin fisheries are linked to the eastern Atlantic and Mediterranean stock. Therefore, management actions taken in the eastern Atlantic and Mediterranean are likely to influence the recovery in the western Atlantic, because even small rates of mixing from East to West can have significant effects on the West due to the fact that Eastern plus Mediterranean resource is much larger than that of the West.

## WEST ATLANTIC BLUEFIN TUNA SUMMARY

## (Catches and Biomass in t)

| Current (2009) Catch (including discards) | 1,935 t |
| :---: | :---: |
| Assuming Low Potential Recruitment |  |
| Maximum Sustainable Yield (MSY) | 2,585 (2,409-2,766) ${ }^{1}$ |
| Relative Spawning Stock Biomass: |  |

* Current Task I figures (2008 and 2009) where the shaded cells indicate which catches have changed since the assessment.

BFT-Figure 1. Geographic distribution of bluefin tuna catches per $5 x 5$ degrees and per main gears.

BFT -East Atlantic stock (Task-I) by region

BFT -EAST Atlantic stock (Task-I )by major gear

BFTE-Figure 1. Reported catch for the East Atlantic and Mediterranean from Task I data from 1950 to 2009 split by main geographic areas (top panel) and by gears (bottom panel) together with unreported catch estimated by the Committee (using from fishing capacity and mean catch rates over the last decade) and TAC levels since 1998.

BFTE-Figure 2. Time series of fishery indicators (CPUE) for the East Atlantic and Mediterranean bluefin tuna stock. All the CPUE series are standardized except the nominal Norway PS series.

BFTE-Figure 3. Fishing mortality (for ages 2 to 5 and 10+), spawning stock biomass (in tons) and recruitment (in number of fish) estimates from VPA runs 13 and 15. Top panel: reported catch; bottom panel: inflated catch.

BFTE-Figure 4. Stock status in the terminal year (2009) estimated from VPA runs 13 and 15 with reported and inflated catch and considering low, medium and high recruitment levels. Clouds of symbols represent the distribution of the terminal year obtained through bootstrapping.

BFTE-Figure 5. Plots of the annual mean weight from the catch-at-size data per main area from 1950 to 2009.

BFTE-Figure 6. Probabilities plot of stock rebuilding at $\mathrm{SSB}_{\mathrm{F} 0.1}$ by years and TAC levels (the probabilities combine the results obtained from the stochastic runs after the 24 scenarios investigated). According to Rec. [09$06]$, red area corresponds to probabilities $<60 \%$ while green area corresponds to probabilities $>60 \%$. Contours for $60 \%, 70 \%, 80 \%$ and $90 \%$ probabilities are further displayed by black lines.

BFTE-Table 1. Probabilities of stock rebuilding at $\mathrm{SSB}_{\mathrm{F} 0.1}$ by years and TAC levels (the probabilities combined the results obtained from the stochastic runs over the 24 scenarios being investigated). The difference in grey colour underlines the catch (TAC) at which the $60 \%$ probability would not be anymore achieved.

BFTW-Figure 1. Historical catches of western bluefin tuna: (a) by gear type and (b) in comparison to TAC levels agreed by the Commission.

BFTW-Figure 2. Historical average weight of bluefin tuna caught by fisheries operating in the western management area.

BFTW-Figure 3. Updated indices of abundance for western bluefin tuna. The dashed portion of the Japanese longline series represents the trend estimated in 2009, which was considered unreliable by the 2010 SCRS.

BFTW-Figure 4. Median estimates of spawning biomass (age 9+), fishing mortality on spawners, apical fishing mortality ( F on the most vulnerable age class) and recruitment for the base VPA model. The $80 \%$ confidence intervals are indicated with dotted lines. The recruitment estimates for the last three years of the VPA are considered unreliable and have been replaced by the median levels corresponding to the low recruitment scenario.

BFTW-Figure 5. Estimated status of stock relative to the Convention objectives (MSY) by year (1970 to 2009). The lines give the time series of point estimates for each recruitment scenario and the cloud of symbols depicts the corresponding bootstrap estimates of uncertainty for the most recent year. The large black circle represents the status estimated for 2009.

BFTW-Figure 6. Projections of spawning stock biomass (SSB) for the Base Case assessment under low recruitment potential (top panels) and high recruitment potential (bottom panels) and various levels of constant catch. The labels " $50 \%$ " and " $60 \%$ " refer to the probability that the SSB will be greater than or equal to the values indicated by each curve. The curves corresponding to each catch level are arranged sequentially in the same order as the legends. A given catch level is projected to have a $50 \%$ or $60 \%$ probability of meeting the convention objective (SSB greater than or equal to the level that will produce the MSY) in the year that the corresponding curve meets the dashed horizontal line.

BFTW-Figure 7. Kobe II matrices giving the chance that the spawning stock biomass (SSB) will exceed the level that will produce MSY in any given year under various constant catch levels for the Base Case assessment under the low recruitment, high recruitment, and combined scenarios. The red, yellow and green regions represent chances of less than $50 \%, 50-59 \%$ and $60 \%$ or better, respectively.

### 8.6 BLUE MARLIN AND WHITE MARLIN

## BUM/WHM-1. Biology

The central and northern Caribbean Sea and northern Bahamas have historically been known as the primary spawning area for blue marlin in the western North Atlantic. Recent reports show that blue marlin spawning can also occur north of the Bahamas in an offshore area near Bermuda at about $32^{\circ}-34^{\circ}$ North. Ovaries of female blue marlin caught by artisanal vessel in Côte d'Ivoire show evidence of pre-spawning and post-spawning, but not of spawning. In this area females are more abundant than males ( $4: 1$ female/male ratio). Coastal areas off West Africa have strong seasonal upwelling, and may be feeding areas for blue marlin.

Previous reports have mentioned spawning of white marlin off southeast Brazil ( $25^{\circ}$ to $26^{\circ} \mathrm{S}$ and $45^{\circ}$ to $45^{\circ} \mathrm{W}$ ) in the same area where blue marlin spawn. In this area blue marlin spawn from April to June and white marlin spawn from December to March. In the northwest Atlantic white marlin have been reported spawning in the Gulf of Mexico in June. Recent reports confirm that white marlin also spawns offshore and north of the Antilles ( $19^{\circ}$ to $23^{\circ} \mathrm{N}$ and $60^{\circ}$ to $70^{\circ} \mathrm{W}$ ) between April and July.

Atlantic blue marlin inhabit the upper parts of the open ocean. Although they spend much of the time on the upper mixed layer they dive regularly to maximum depths of around 300 m , with some vertical excursions down to 800 m . They do not confine themselves to a narrow range of temperatures but most tend to be found in waters warmer than $17^{\circ} \mathrm{C}$. The distributions of times at depth are significantly different between day and night. At night, the fish spent most of their time at or very close to the surface. During daylight hours, they are typically below the surface, often at 40 to $100+\mathrm{m}$. These patterns, however, can be highly variable between individuals and also vary depending on the temperature and dissolved oxygen of the surface mixed layer. This variability in the use of habitat by marlins indicates that simplistic assumptions about habitat usage made during the standardization of CPUE data may be inappropriate.

All biological material sampled to date from white marlin, prior to the confirmation of the existence of roundscale spearfish (T. georgii) in 2006, contains unknown mixture of the round scale spearfish and white marlin. Therefore reproductive parameters, growth curves and other biological studies previously thought to describe white marlin may not exclusively represent this species.

## BUM/WHM-2. Fishery indicators

It has now been confirmed that white marlin landings reported to ICCAT include roundscale spearfish in significant numbers, so that historical statistics of white marlin include a mixture of two species. Studies of white marlin/roundscale spearfish ratios have been conducted, with overall estimated ratios between $23-27 \%$. Previously, these were thought to represent only white marlin. In some areas however only one species is present in these samples.

The geographic distribution of the catches is given in BUM/WHM-Figure 1. The Committee used Task I catches as the basis for the estimation of total removals (BUM/WHM-Figure 2). Total removals for the period 1990-2004 were obtained during the 2006 assessment by modifying Task I values with the addition of blue marlin and white marlin that the Committee estimated from catches reported as billfish unclassified. Additionally the reporting gaps were filled with estimated values for some fleets. Estimates of total removals since 2005 only represent task I data.

During the 2006 marlin assessment (Anon. 2007b) it was noted that catches of blue marlin and white marlin continued to decline through 2004. Over the last 15 years, Antillean artisanal fleets have increased the use of Moored Fish Aggregating Devices (MFADs) to capture pelagic fish. Catches of blue marlin caught around MFADs are known to be significant but reports on these catches made to ICCAT are very incomplete. Recent reports from purse seine fleets in West Africa suggest that blue marlin is more commonly caught with tuna schools associated with FADs than with free tuna schools. Task I catches of blue marlin (BUM/WHM-Table 1) in 2009 were $-2,863 \mathrm{t}$. In 2008, Task I catches of blue marlin were $4,138 \mathrm{t}$. Task I catches of white marlin in 2008 and 2009 were 374 t and 406 t , respectively (BUM/WHM-Table 2). Task I catches of white marlin and blue marlin for 2009 are preliminary. Historical reports of unclassified billfish remain an important issue in the estimation of historical removals from marlin stocks.

A number of relative abundance indices were estimated during the blue marlin 2010 data preparatory Meeting. However, given the apparent shift in landings from industrial to non-industrial fleets in recent times, it is imperative that CPUE indices are developed for all fleets that have substantial landings.

During the 2006 assessment combined indices for both species were estimated to have declined during the period 1990-2004. However, the trends for 2001-2004 suggest that the decline in abundance of blue marlin may have slowed or halted, and that the decline in white marlin may have reversed, with abundance increasing slightly in the most recent years. Trends in white marlin may also inadvertently reflect trends in the abundance of roundscale spearfish. As evidenced by differences between the trends from the individual and combined indices, four years is likely to be too short a period to reach definitive conclusions about abundance trends. Several years of additional data will be required to confirm recent changes in these abundance trends. Relative abundance indices recently developed for blue marlin from CPUE data for a sport fishery in southeastern Brazil, and for the artisanal fishery off Côte d'Ivoire do not appear to conflict with the conclusions of the assessment of blue marlin made in 2006.

## BUM/WHM-3. State of the stocks

## Blue marlin

No new information on stock status has been provided since the 2006 assessment (Anon. 2007b). The recent biomass level most likely remains well below the $\mathrm{B}_{\mathrm{MSY}}$ estimated in 2000. Current and provisional diagnoses suggest that F declined during 2000-2004 and was possibly smaller than $\mathrm{F}_{\text {replacement }}{ }^{1}$ but larger than the $\mathrm{F}_{\text {MSY }}$ estimated in the 2000 assessment. Over the period 2001-2005 several abundance indicators suggest that the decline has been at least partially arrested, but some other indicators suggest that abundance has continued to decline. During the 2010 ICCAT Blue Marlin Data Preparatory Meeting, catch rate information was updated by the presentation of five new standardized catch rate indices, and the inclusion of a historical catch rate index from the sport fishery from Venezuela (BUM-WHM-Figure 3). The 2011 stock assessment, might confirm if these recent apparent changes in trend have continued.

## White marlin

No new information on stock status has been provided since the 2006 assessment (Anon. 2007b). The biomass for 2000-2004 most likely remained well below the $\mathrm{B}_{\mathrm{MSY}}$ estimated in the 2002 assessment. During the last assessment, it was estimated that F 2004 was probably smaller than $\mathrm{F}_{\text {replacement }}$ and probably also larger than the $\mathrm{F}_{\text {MSY }}$ estimated in the 2002 assessment. Over the period 2001-2004 combined longline indices and some individual fleet indices suggest that the decline has been at least partially reversed, but some other individual fleet indices suggest that abundance has continued to decline. The next stock assessment, might confirm if these recent apparent changes in trend have continued. However, this will require developing a mechanism to separate landings of white marlin from roundscale spearfish. All historical indices of abundance of white marlin may inadvertently have included an unknown quantity of roundscale spearfish.

## BUM/WHM-4. Outlook

No new information on the recovery/outlook for marlins has been provided since the 2006 assessment (Anon. 2007b). The Commission's current management plan has the potential of recovering the stocks of blue marlin and white marlin to the $\mathrm{B}_{\text {MSY }}$ level. However, reports of recent increases in catches of blue marlin by artisanal fisheries in both sides of the Atlantic may negate the effectiveness of the ICCAT plan that aims to recover this stock.

The last stock assessment suggested that the recovery of blue marlin stock might proceeded faster than would have been estimated at the 2000 assessment (Anon. 2001), provided catches remain at the level estimated for 2004. Some signs of stabilization in the abundance trend are apparent in the most recent catch per unit of effort data of blue marlin (2000-2004). Similarly, some signs of a recovery trend are apparent in the most recent catch per unit of effort data for white marlin (2000-2004), although recent information suggests that these data may inadvertently have included roundscale spearfish.

[^2]It should be noted that these trends are based only on a few years of observations. Confirmation of these recent apparent changes in abundance trends of white marlin and blue marlin are needed.

The presence of unknown quantities of roundscale spearfish in the biological parameters, historical landings and relative abundance estimates of white marlin make the stock status and outlook for this species more uncertain.

## BUM/WHM-5. Effect of current regulations

Recommendations [Rec. 00-13], [Rec. 01-10] and finally [Rec. 02-13] placed additional catch restrictions for blue marlin and white marlin. The latter established that "the annual amount of blue marlin that can be harvested by pelagic longline and purse seine vessels and retained for landing must be no more than $33 \%$ for white marlin and $50 \%$ for blue marlin of the 1996 or 1999 landing levels, whichever is greater". That recommendation established that, "All blue marlin and white marlin brought to pelagic longline and purse seine vessels alive shall be released in a manner that maximizes their survival. The provision of this paragraph does not apply to marlins that are dead when brought along the side of the vessel and that are not sold or entered into commerce". The Committee estimated the catch of pelagic longline vessels for a subset of fleets that the Committee thought would be expected to be affected by Recommendations [Rec. 00-13] and [Rec. 02-13]. Catches of these fleets represent, $97 \%$ of all longline caught blue marlin and $93 \%$ of all longline caught white marlin for the period 1990-2007. Catches of both species have declined since 1996-99, the period selected as the reference period by the recommendations. Since 2002, the year of implementation of the last of these two recommendations, the catch of blue marlin has been below the $50 \%$ value recommended by the Commission. Similarly, the catch of white marlin since 2002 has been at about the $33 \%$ value recommended by the Commission (BUM/WHMFigure 4). This analysis represents only longline caught marlin even though the recommendations referred to the combined catch of pelagic longline and purse seine because the catch estimates of billfish by-catch from purse seine vessels are more uncertain than those from longline. Over the period considered, purse seine caught marlin represent $2 \%$ of the total catch reported by the combination of purse seine and pelagic longline.

Some fisheries/fleets are using circle hooks, which can minimize deep hooking and increase the survival of marlins hooked on longlines and recreational gear. More countries have started reporting data on live releases in 2006. Additionally, more information has come about, for some fleets, on the potential for using gear modifications to reduce the by-catch and increase the survival of marlins. Such studies have also provided information on the rates of live releases for those fleets. However there is not enough information on the proportion of fish being released alive for all fleets, to evaluate the effectiveness of the ICCAT recommendation relating to the live release of marlins.

## BUM/WHM-6. Management recommendations

- The Commission should, at a minimum, continue the management measures already in place because marlins have not yet recovered.
- The Commission should take steps to assure that the reliability of the recent fishery information improves in order to provide a basis for verifying possible future rebuilding of the stocks. Improvements are needed in the monitoring of the fate and amount of dead and live releases, with verification from scientific observer programs; verification of current and historical landings from some artisanal and industrial fleets; and complete and updated relative abundance indices from CPUE data for the major fleets.
- The Commission should consider requiring the reporting of roundscale spearfish catches separate from white marlin.
- Should the Commission wish to increase the likelihood of success of the current management measures of the marlin rebuilding plan, further reduction in mortality would be needed, for example by:
- implementing plans to improve compliance of current regulations,
- encouraging the use of alternative gear configurations that reduce the likelihood of deep hooking. Depending on the fisheries/fleets, such reductions may be achievable by making changes in hook type, bait type or a combination of the two,
- broader application of time/area catch restrictions.
- Given the recent importance of the catch from artisanal fisheries, and to increase the likelihood of recovery of marlin stocks, the Commission should consider regulations that control or reduce the fishing mortality generated by these fisheries.
- While substantial research into habitat requirements of blue and white marlin have been undertaken since the last assessments, the results of this research are not yet sufficient to allow the Committee to reach scientific consensus on the best method for directly estimating MSY benchmarks for these species based on the complete time-series of data. The Commission should encourage continued research on development of methods to incorporate this information into stock assessments in order to provide a basis for increasing the certainty with which management advice can be provided.

| Atlantic Blue Marlin and Atlantic White Marlin Summary |  |  |

BUM (2000-2008)

BUM-WHM-Figure 1a. Geographic distribution of mean blue marlin catch (2000-2008) by major gears. This does not include provisional 2009 data, including the large artisanal landing from the FAD fishery off Martinique and Guadalupe, France. For details, see BUM-WHM-Table 1.

BUM-WHM-Figure 1b. Geographic distribution of mean white marlin catch (2000-2008) by major gears.

BUM-WHM-Figure 2. Total catch of blue marlin and white marlin reported in Task I.

BUM-WHM-Figure 3. Blue marlin standardized CPUE's presented during the BUM data preparatory meeting. Some of the major offshore longline fleets are not included (i.e., Japan, Korea, and ChineseTaipei).

BUM-WHM-Figure 4. Estimates of pelagic longline catch for blue marlin and white marlin for the period 1990-2007 and reference catch levels relevant to ICCAT recommendations [Rec. 00-13] and [Rec. 02-13]. Base is defined as the maximum of either the 1996 or 1999 catch of marlins, whichever is greatest. Recommendation calls for a reduction in marlin catch in comparison to this base. The reduction recommended for blue marlin was $50 \%$ and for white marlin $67 \%$.

### 8.7 SAI - SAILFISH

Sailfish (Istiophorus platypterus) has a pan-tropical distribution. ICCAT has established, based on life history information on migration rates and geographic distribution of catch, that there are two management units for Atlantic sailfish, eastern and western (SAI-Figure 1). The first successful assessment that estimated reference points for eastern and western sailfish stocks was conducted in 2009.

## SAI-1. Biology

Larval sailfish are voracious feeders initially feeding on crustaceans from the zooplankton but soon switching to a diet of fish larvae. Temperature preferences for adult sailfish appear to be in the range of $25-28^{\circ} \mathrm{C}$. A study undertaken in the Strait of Florida and the southern Gulf of Mexico indicated that habitat preferences from satellite tagged sailfish were primarily within the upper $20 \sim 50 \mathrm{~m}$ of the water column. The tag data also indicated common short-term movements to depths in excess of 100 m , with some dives as deep as 350 m . Sailfish is the most coastal of all billfish species and conventional tagging data suggest that they move shorter distances than the other billfish (SAI-Figure 2). Sailfish grow rapidly and reach a maximum size of 160 cm for males and 220 cm for females, with females reaching maturity at 155 cm . Sailfish reach a maximum age of at least 17 years.

Sailfish spawn over a wide area and year around. In the North, evidence of spawning has been detected in the Straits of Florida, and off the Venezuelan, Guyanese and Surinamese coasts. In the southwest Atlantic, spawning occurs off the southern coast of Brazil between $20^{\circ}$ and $27^{\circ} \mathrm{S}$, and in the east Atlantic, off Senegal and Côte d'Ivoire. Timing of spawning can differ between regions. From the Florida Straits to the areas off Guyana sailfish spawn in the second semester of the year, whist in the southwestern Atlantic and the tropical eastern Atlantic they spawn late and early in the year.

## SAI-2. Description of the fisheries

Sailfish are targeted by coastal artisanal and recreational fleets and, to a less extent, are caught as by-catch in longline and purse seine fisheries (SAI-Figure 1). Historically, catches of sailfish were reported together with spearfish by many longline fleets. In 2009 these catches were separated by the Species Group (SAI-Table 1). Historical catches of unclassified billfish continue to be reported to the Committee making the estimation of sailfish catch difficult. Catch reports from countries that have historically been known to land sailfish continue to suffer from gaps and there is increasing ad-hoc evidence of un-reported landings in some other countries. These considerations provide support to the idea that the historical catch of sailfish has been under-reported, especially in recent times where more and more fleets encounter sailfish as by-catch or target them.

Reports to ICCAT estimate that the Task I catch for 2009 was $1,640 \mathrm{t}$ and $1,415 \mathrm{t}$ for the east and west stocks, respectively (SAI-Figure 3). Task I catches of sailfish for 2009 are preliminary because they do not include reports from all fleets.

## SAI-3. State of the stocks

ICCAT recognizes the presence of two stocks of sailfish in the Atlantic, the eastern and western stocks. There is increasing evidence that an alternative stock structure with a north western stock and a south/eastern stock should be considered. Assessments of stocks based on the alternative stock structure option have not been done to date, however, conducting them should be a priority for future assessments.

In 2009 ICCAT conducted a full assessment of both Atlantic sailfish stocks SCRS/2009/012 through a range of production models and by using different combinations of relative abundance indices (SAI-Figure 4). It is clear that there remains considerable uncertainty regarding the stock status of these two stocks, however, many assessment model results present evidence of overfishing and evidence that the stocks are overfished, more so in the east than in the west. Although some of the results suggest a healthy stock in the west, few suggest the same for the east. The eastern stock is also assessed to be more productive than the western stock, and probably able to provide a greater MSY. The eastern stock is likely to be suffering stronger overfishing and most probably has been reduced further below the level that would produce the MSY than the western stock. Reference points obtained with other methods reach similar conclusions.

Examination of recent trends in abundance suggests that both the eastern and western stocks suffered their greatest declines in abundance prior to 1990. Since 1990, trends in relative abundance conflict between different indices, with some indices suggesting declines, other increases and others not showing a trend (SAI-Figure 4). Examination of available length frequencies for a range of fleets show that average length and length distributions do not show clear trends during the period where there are observations. A similar result was obtained in the past for marlins. Although it is possible that, like in the case of the marlins, this reflects the fact that mean length is not a good indicator of fishing pressure for billfish it could also reflect a pattern of high fishing pressure over the period of observation.

## SAI-4. Outlook

Both the eastern and western stocks of sailfish may have been reduced to stock sizes below $\mathrm{B}_{\text {msy }}$. There is considerable uncertainty on the level of reduction, particularly for the west, as various production model fits indicated the biomass ratio $\mathrm{B}_{2007} / \mathrm{B}_{\mathrm{MSY}}$ both above and below 1.0. The results for the eastern stock were more pessimistic than those for the western stock in that more of the results indicated recent stock biomass below $\mathrm{B}_{\text {MSY }}$. Therefore there is particular concern over the outlook for the eastern stock.

## SAI-5. Effect of current regulations

No ICCAT regulations for sailfish are in effect, however, some countries have established domestic regulations to limit the catch of sailfish. Among these regulations are: requirement of releasing all billfish from longline vessels, minimum size restrictions, circle hooks and catch and release strategies in sport fisheries.

## SAI-6. Management recommendations

The Committee recommends that catches for the eastern stock should be reduced from current levels. It should be noted, however, that artisanal fishermen harvest a large part of the sailfish catch along the African coast.

The Committee recommends that catches of the western stock of sailfish should not exceed current levels. Any reduction in catch in the West Atlantic is likely to help stock re-growth and reduce the likelihood that the stock is overfished. It should be noted, however, that artisanal fishermen harvest a large part of the sailfish catch of the western sailfish stock.

The Committee is concerned about the incomplete reporting of sailfish catches, particularly for the most recent years, because it increases uncertainty in stock status determination. The Committee recommends all countries landing or having dead discards of sailfish, report these data to the ICCAT Secretariat.

## ATLANTIC SAILFISH SUMMARY

|  | West Atlantic | East Atlantic |
| :--- | :--- | :--- |
| Maximum Sustainable Yield (MSY) | $600-1,100^{1} \mathrm{t}$ | $1,250-1,950^{1} \mathrm{t}$ |
| 2009 Catches (Provisional) | $1,415 \mathrm{t}$ | $1,640 \mathrm{t}$ |
| $\mathrm{B}_{2007} / \mathrm{B}_{\mathrm{MSY}}$ | Possibly $<1.0$ | Likely $<1.0$ |
| $\mathrm{~F}_{2007} / \mathrm{F}_{\text {MSY }}$ | Possibly $>1.0$ | Likely $>1.0$ |
| 2008 Replacement Yield | not estimated | not estimated |
| Management Measures in Effect | None $^{2}$ | None $^{2}$ |

### 8.8 SWO-ATL-ATLANTIC SWORDFISH

The last assessment for Atlantic swordfish was conducted in 2009 (SCRS/2009/016). Other information relevant to Atlantic swordfish is presented in the Report of the Sub-Committee on Statistics, included as Appendix 8 to this SCRS Report, and recommendations pertinent to Atlantic swordfish are presented in Section 15.

## SWO-ATL-1. Biology

Swordfish (Xiphias gladius) are members of the family Xiphiidae and are in the suborder Scombroidei. They can reach a maximum weight in excess of 500 kg . They are distributed widely in the Atlantic Ocean and Mediterranean Sea. In the ICCAT convention area, the management units of swordfish for assessment purposes are a separate Mediterranean group, and North and South Atlantic groups separated at $5^{\circ} \mathrm{N}$. This stock separation is supported by recent genetic analyses. However, the precise boundaries between stocks are uncertain, and mixing is expected to be highest at the boundary in the tropical zone. Swordfish feed on a wide variety of prey including groundfish, pelagic fish, deep-water fish, and invertebrates. They are believed to feed throughout the water column, and from recent electronic tagging studies, undertake extensive diel vertical migrations.

Swordfish mostly spawn in the western warm tropical and subtropical waters throughout the year, although seasonality has been reported in some of these areas. They are found in the colder temperate waters during summer and fall months. Young swordfish grow very rapidly, reaching about 140 cm LJFL (lower-jaw fork length) by age three, but grow slowly thereafter. Females grow faster than males and reach a larger maximum size. Tagging studies have shown that some swordfish can live up to 15 years. Swordfish are difficult to age, but about $50 \%$ of females were considered to be mature by age five, at a length of about 180 cm . However, the most recent information indicates a smaller length and age at maturity.

## SWO-ATL-2. Fishery indicators

Due to the broad geographical distribution of Atlantic swordfish (SWO ATL-Figure 1) in coastal and off-shore areas (mostly ranging from $50^{\circ} \mathrm{N}$ to $45^{\circ} \mathrm{S}$ ), this species is available to a large number of fishing countries (SWO ATL-Figure 2). Directed longline fisheries from Canada, EU-Spain, and the United States have operated since the late 1950s or early 1960s, and harpoon fisheries have existed at least since the late 1800s. Other directed swordfish fisheries include fleets from Brazil, Morocco, Namibia, EU-Portugal, South Africa, Uruguay, and Venezuela. The primary by-catch or opportunistic fisheries that take swordfish are tuna fleets from Chinese Taipei, Japan, Korea and EU-France. The tuna longline fishery started in 1956 and has operated throughout the Atlantic since then, with substantial catches of swordfish that are produced as a by-catch of tuna fisheries. The largest proportion of the Atlantic catches is made using surface-drifting longline. However, many additional gears are used, including traditional gillnets off the coast of western Africa.

## Total Atlantic

The total Atlantic estimated catch (landings plus dead discards) of swordfish (North and South, including reported dead discards) in 2009 ( $25,103 \mathrm{t}$ ) represented a slight increase from that in 2008 ( $23,551 \mathrm{t}$ ). As a small number of countries have not yet reported their 2009 catches and because of unknown unreported catches, this value should be considered provisional and subject to further revision.

In an effort to quantify possible unreported catches in the Convention area during the 2009 stock assessment, the ICCAT Statistical Document data base was examined. The use of this information was complicated because of the lack of conversions factors available for products such as loin, fillet, and gilled/gutted swordfish. The comparison between the swordfish Statistical Document System (s.SDS) data from 2003 through 2007 and the reported Task I by flag indicates that Task I catches might not represent the total landed catch of Convention area swordfish, although the extent to which this occurs was highly uncertain. The largest discrepancy between the data sources is for flags with an unknown area of capture, and amounts to nearly 21,000 t over the 2003-2007 time period. Considering only the s.SDS data classified as coming from the Convention area, the discrepancy amounts to an estimate of less than $1,000 \mathrm{t}$ over the time period. The comparison implies that international trade of Convention Area landed swordfish might represent less than $13 \%$ of the landed catch recorded in Task I and that a surprisingly low number of Contracting Parties engage in export of Convention area swordfish.

## North Atlantic

For the past decade, the North Atlantic estimated catch (landings plus dead discards) has averaged about 11,332 t per year (SWO-ATL-Table 1 and SWO-ATL-Figure 3). The catch in 2009 (12,655 t) represents a $37 \%$ decrease since the 1987 peak in North Atlantic landings ( $20,236 \mathrm{t}$ ). These reduced landings have been attributed to ICCAT regulatory recommendations and shifts in fleet distributions, including the movement of some vessels in certain years to the South Atlantic or out of the Atlantic. In addition, some fleets, including at least the United States, EU-Spain, EU-Portugal and Canada, have changed operating procedures to opportunistically target tuna and/or sharks, taking advantage of market conditions and higher relative catch rates of these species previously considered as by-catch in some fleets. Recently, socio-economic factors may have also contributed to the decline in catch.

Trends in nominal catch rates by fleets contributing to the production model are shown in SWO-ATL-Figure 4. Most of the series have an increasing trend since the late 1990s, but the U.S. catch rates remained relatively flat. There have been some recent changes in United States regulations that may have impacted catch rates, but these effects remain unknown.

The 2010 Swordfish Species Group reviewed new information from Canada, which updated its nominal catch rate series for the pelagic longline fishery (SCRS/2010/139). The nominal CPUE increased from 2008 to 2009, continuing the increasing trend that commenced in 1996. The Group agreed with the authors' view that more work was needed to reflect changes in management and targeting practices. It was suggested that since the switch from a competitive fishery to an Individual Transferable Quota based-system occurred in 2002, sufficient time has passed to consider breaking the time series into two, reflecting the two periods of contrasting management approaches.

The most frequently occurring ages in the catch include ages 2 and 3 (SWO-ATL-Figure 5). There are reports of increasing average size of the catch in some North Atlantic fisheries, including United States and Canada.

## South Atlantic

The historical trend of catch (landings plus dead discards) can be divided in two periods: before and after 1980. The first one is characterized by relatively low catches, generally less than $5,000 \mathrm{t}$ (with an average value of 2,300 t). After 1980, landings increased continuously up to a peak of $21,930 \mathrm{t}$ in 1995 , levels that are comparable to the peak of North Atlantic harvest (20,236 t). This increase of landings was, in part, due to progressive shifts of fishing effort to the South Atlantic, primarily from the North Atlantic, as well as other waters. Expansion of fishing activities by southern coastal countries, such as Brazil and Uruguay, also contributed to this increase in catches. The reduction in catch following the peak in 1995 resulted from regulations and partly due to a shift to other oceans and target species. In 2009, the $12,448 \mathrm{t}$ reported catches were about $44 \%$ lower than the 1995 reported level (SWO-ATL-Figure 3).

The SCRS noted that there was a considerable decline in the magnitude of the catch by Namibia in 2009 compared with 2008 ( 25 and 518 t , respectively) that appeared inconsistent with recent developments in capacity. Namibian authorities will be contacted with a request for an explanation for this apparent anomaly.

As observed in the 2006 assessment, the CPUE trend from targeted and non-targeted fisheries show different trends and high variability which indicates that at least some are not depicting trends in the abundances of the stock (SWO-ATL-Figure 6). It was noted that there was little overlap in fishing area and strategies between the by-catch and targeted fleets used for estimating CPUE pattern, and therefore the by-catch and targeted fisheries CPUE trends could be tracking different components of the population.

## Discards

Since 1991, several fleets have reported dead discards (see SWO-ATL-Table 1). The volume of Atlantic-wide reported discards since then has ranged from 151 t to $1,139 \mathrm{t}$ per year. Reported annual dead discards have been declining in recent years.

## SWO-ATL-3. State of the stocks

## North Atlantic

Results from the base case production model are shown in SWO-ATL-Figure 7. The estimated relative biomass trend shows a consistent increase since 2000. The current results indicate that the stock is at or above $\mathrm{B}_{\text {MSY }}$. The relative trend in fishing mortality shows that the level of fishing peak in 1995, followed by a decrease until 2002, followed by small increase in the 2003-2005 period and downward trend since then. Fishing mortality has been below $\mathrm{F}_{\text {MSY }}$ since 2005. The results suggest that there is greater than $50 \%$ probability that the stock is at or above $\mathrm{B}_{\mathrm{MSY}}$, and thus the Commission's rebuilding objective [Rec. 99-02] has been achieved (SWO-ATL-Figure 8). However, it is important to note that since 2003 the catches have been below the TAC's greatly increasing the chances for a fast recovery. Overall, the stock was estimated to be somewhat less productive than the previous assessment, with the intrinsic rate of increase, $r$, estimated at 0.44 compared to 0.49 in 2006.

Other analyses conducted by the SCRS (Bayesian surplus production modeling, and Virtual Population Analyses) generally support the results described for the base case surplus production model above.

## South Atlantic

The results of the base case production model indicated that there were conflicting signals for several of the indices used. The model estimated overall index was relatively stable until the early 1980s when it started declining until the late 1990's and it reversed that trend about 2003. Estimated relative fishing mortality $\left(\mathrm{F}_{2008} / \mathrm{F}_{\text {MSY }}\right)$ was 0.75 indicating that the stock is not being overexploited. Estimated relative biomass ( $\mathrm{B}_{2009} / \mathrm{B}_{\mathrm{MSY}}$ ) was 1.04 (SWO-ATL-Figure 9), indicating that the stock was not overexploited.

Because of the high level of uncertainty associated with the south Atlantic production models results, the SCRS conducted catch-only modeling analysis, including two explorations using different assumptions concerning the intrinsic rate of population increase. The distribution for MSY was skewed for both runs (SWO-ATL-Figure 10). The median of MSY estimated for RUN 1 was $18,130 \mathrm{t}$ and for RUN 2 was $17,934 \mathrm{t}$. SWO-ATL-Figure 11 summarizes recent stock status, as determined from the catch-only model.

## SWO-ATL-4. Outlook

## North Atlantic

The base production model was projected to the year 2018 under constant TAC scenarios of 10, 11, 12, 13, 14 and 15 thousand tones. Catch in year 2009 was assumed to be the average of the last three years (2006-08) $(11,515 \mathrm{t})$. The actual reported landings in 2009 were $12,655 \mathrm{t}$. Median trajectories for biomass and fishing mortality rate for all of the future TAC scenarios are plotted in SWO-ATL-Figure 12.

Future TACs above MSY are projected to result in $50 \%$ or lower probabilities of the stock biomass remaining above $\mathrm{B}_{\text {MSY }}$ over the next decade (SWO-ATL-Figure 13) as the resulting probability of $F$ exceeding $\mathrm{F}_{\text {MSY }}$ for these scenarios would trend above $50 \%$ over time. A TAC of 13,000 t would provide approximately a $75 \%$ probability of maintaining the stock at a level consistent with the Convention objective over the next decade.

## South Atlantic

Projections for the base case production model were performed for catch levels from $10,000 \mathrm{t}$ to $16,000 \mathrm{t}$ by increments of $1,000 \mathrm{t}$ for 2010-2020. For 2009, all projection scenarios assumed a catch equal to the average catch for 2006-2008 (13,658 t). SWO-ATL-Figure 14 shows the results of the projections. Because the SCRS considers that the production model estimated benchmarks are poorly estimated, the projections are shown as biomass changes rather than relative biomass. In general, catches of $14,000 \mathrm{t}$ or less will result in increases in the biomass of the stock; catches on the order of 15,000 will maintain the biomass of the stock at approximately stable levels during the period projected. Catches on the order of $16,000 \mathrm{t}$ or more will result in biomass decrease. The current TAC is $17,000 \mathrm{t}$.

For the catch only model projections, constant catch scenarios were evaluated ranging from 10,000 to $17,000 \mathrm{t}$, incremented by $1,000 \mathrm{t}$ for a period of 10 years. For 2009, all projection scenarios assumed a catch equal to the average catch for 2006-2008 (13,658 t). In general, catches of $15,000 \mathrm{t}$ will result in the biomasses being higher
than $\mathrm{B}_{\text {MSY }} 80 \%$ of the time. SWO-ATL-Figure 15 summarizes the probability of $\mathrm{B}>\mathrm{B}_{\text {MSY }}$ and $\mathrm{F}<\mathrm{F}_{\text {MSY }}$ for the constant catch scenarios indicated over time. Catches on the order of 17,000 will result in a probability of 0.67 of the biomass being above $\mathrm{B}_{\mathrm{MSY}}$ in ten years.

## SWO-ATL-5. Effects of current regulations

In 2006, the Committee provided information on the effectiveness of existing minimum size regulations. New catch regulations were implemented on the basis of Rec. 06-02, which entered into effect in 2007 (Rec. 08-02 extended the provisions of Rec. 06-02 to include 2009). Finally, Rec. 09-02 came into effect in 2010 and extended most of the provisions of Rec. 06-02 for one year only.

## Catch limits

The total allowable catch in the North Atlantic during the 2007 to 2009 period was $14,000 \mathrm{t}$ per year. The reported catch during that period averaged $12,096 \mathrm{t}$ and did not exceed the TAC in any year. Reports for 2009 are considered provisional and subject to change.

The total allowable catch in the South Atlantic for the years 2007 through 2009 was $17,000 \mathrm{t}$. The reported catch during that period averaged $13,455 \mathrm{t}$, and did not exceed the TAC in any year. Reports for 2009 are considered provisional and subject to change.

## Minimum size limits

There are two minimum size options that are applied to the entire Atlantic: 125 cm LJFL with a $15 \%$ tolerance, or 119 cm LJFL with zero tolerance and evaluation of the discards.

For the 2006-2008 period, the estimate of the percentage of swordfish reported landed (throughout the Atlantic) less than 125 cm LJFL was about $24 \%$ (in number) overall for all nations fishing in the Atlantic ( $28 \%$ in the northern stock and $20 \%$ in southern stock). If this calculation is made using reported landings plus estimated dead discards, then the percentage less than 125 cm LJFL would be of the same order given the relatively small amount of discards reported. These estimates are based on the overall catch at size, which have high levels of substitutions for a significant portion of the total catch.

## Other implications

The Committee is concerned that in some cases national regulations have resulted in the unreported discarding of swordfish caught in the North stock and, to a certain extent, could have influenced similar behavior of the fleet that fishes the South Atlantic swordfish stock. The Committee considers that these regulations may have had a detrimental effect on the availability and consistency of scientific data on catches, sizes and CPUE indices of the Atlantic fleet. The Committee expressed its serious concern over this limitation on data for future assessments.

## SWO-ATL-6. Management recommendations

## North Atlantic

Consistent with the goal of the Commission's swordfish rebuilding plan [Rec. 96-02], in order to maintain the northern Atlantic swordfish stock at a level that could produce MSY, with greater than $50 \%$ probability, the Committee recommended reducing catch limits allowed by Rec. 06-02 (15,345 t) to no more than $13,700 \mathrm{t}$, which reflects the current best estimate of maximum yield that could be harvested from the population under existing environmental and fishery conditions. Should the Commission wish to have greater assurance that future biomass would be at or above $\mathrm{B}_{\text {MSY }}$ while maintaining F at or below $\mathrm{F}_{\mathrm{MSY}}$, the Commission should select a lower annual TAC, depending on the degree of precaution the Commission chooses to apply in management.

The Committee noted that allowable catch levels agreed in [Recs. 06-02 and 08-02] exceeded scientific recommendations. The successful rebuilding of this stock could have been compromised if recent catches had been higher than realized.

## South Atlantic

Until sufficiently more research has been conducted to reduce the high uncertainty in stock status evaluations for the southern Atlantic swordfish stock, the Committee emphasizes that annual catch should not exceed the provisionally estimated MSY $(15,000)$. Considering the unquantified uncertainties and the conflicting indications for the stock, the Committee recommends a more precautionary Fishery Management approach, to limit catches to the recent average level ( $\sim 15,000 \mathrm{t}$ ), which are expected to maintain the catch rates at about their current level.

## ATLANTIC SWORDFISH SUMMARY

|  | North Atlantic | South Atlantic |
| :--- | :--- | :--- |
| Maximum Sustainable Yield ${ }^{1}$ | $13,730 \mathrm{t}(13,020-14,182)^{3}$ | $\sim 15,000 \mathrm{t}$ |
| Current (2009) TAC | $14,000 \mathrm{t}$ | $15,000 \mathrm{t}$ |

SWO-ATL-Figure 7. North Atlantic swordfish, biomass, fishing mortality and relative ratio trends for the base production model. The solid lines represent point estimates and broken lines represent estimated $80 \%$ bias corrected confidence intervals.

SWO-ATL-Figure 8. Summary figure of the current northern Atlantic swordfish stock status which includes different representation of the bootstraps results of the base ASPIC model: percentage, phase-plots (marked dot corresponds to the deterministic result) and stock status trajectories for the period 1950-2008. The x-axis represents relative biomass, and the $y$-axis relative exploitation rate.

SWO-ATL Figure 9. South Atlantic, relative biomass ( $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ ) and relative fishing mortality ( $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ ) trajectories estimated by the base case production model.

SWO-ATL-Figure 10. Posterior probability density estimates of MSY for South Atlantic swordfish from the catchonly model fitted to catch data from 1950 to 2009. Run 1 and 2 refer to two scenarios with different assumptions for the intrinsic rate of population increase.

SWO-ATL-Figure 11. Summary figure of the current southern Atlantic swordfish stock status which includes the level of uncertainty on the knowledge of the state of the stock. Conditioned only on the catches, the model estimated a probability of 0.78 that the stock is not overfished and it is not undergoing overfishing.

SWO-ATL-Figure 12. Projections of median relative North Atlantic swordfish stock biomass and F from the base ASPIC model under different constant catch scenarios ( $10 \backslash 15$ thousand tons) North Atlantic swordfish stock.

SWO-ATL-Figure 13. North Atlantic swordfish, probability contours of $\mathrm{B} \geq \mathrm{B}_{\text {MSY }}$ and $\mathrm{F} \leq \mathrm{F}_{\text {MSY }}$ for the constant catch scenarios indicated over time. Red areas represent probabilities less than $50 \%$, yellow from $50-75 \%$, and green above $75 \%$. The $90^{\text {th }}, 75^{\text {th }}, 60^{\text {th }}$, and $50^{\text {th }}$ probability contours are also depicted.

SWO-ATL-Figure 14. South Atlantic, projected biomass levels under various catch scenarios. The bottom panel provides the details of the projections over a reduced time interval.

SWO-ATL-Figure 15. South Atlantic swordfish, probability contours of $\mathrm{B}>\mathrm{B}_{\text {MSY }}$ and $\mathrm{F}<\mathrm{F}_{\text {MSY }}$ (from the catch only model, both runs combined) for the constant catch scenarios indicated over time. Yellow areas represent probabilities from $50-75 \%$, and green above $75 \%$. The 90th, 75th, probability contours are also depicted. No probabilities were below $50 \%$.

### 8.9 SWO-MED-MEDITERRANEAN SWORDFISH

In the last 15 years Mediterranean swordfish production fluctuates without any specific trend at levels higher than those observed for bigger areas such as the North and South Atlantic. The most recent assessment was conducted in 2010, making use of catch and effort information through 2008. The present report summarizes assessment results and readers interested in more detailed information on the state of the stock should consult the report of the latest stock assessment session.

## SWO-MED-1. Biology

Research results based on genetic studies have demonstrated that Mediterranean swordfish compose a unique stock separated from the Atlantic ones, although there is incomplete information on stock mixing and boundaries. However, mixing between stocks is believed to be low and generally limited to the region around the Straits of Gibraltar.

According to previous knowledge, the Mediterranean swordfish have different biological characteristics compared to the Atlantic stock, The growth parameters are different, and the sexual maturity is reached at younger ages than in the Atlantic, although more recent information for the Atlantic indicates that these differences may smaller than was previously thought. In the Mediterranean, mature females as small as 110 cm LJFL have been observed and the estimated size at which $50 \%$ of the female population is mature occurs at about 140 cm . According to the growth curves used by SCRS in the past for Mediterranean swordfish, these two sizes correspond to 2 and 3.5 year-old fish, respectively. Males reach sexual maturity at smaller sizes and mature specimens have been found at about 90 cm LJFL. Based on the fish growth pattern and the assumed natural mortality rate of 0.2 , the maximum yield would be obtained through instantaneous fishing at age 6 , while current catches are dominated, in terms of number, by fish less than 4 years old.

## SWO-MED-2. Fishery indicators

Annual catch levels fluctuate between 12,000-16,000 t. in the last 15 years without any specific trend. Those levels are relatively high and similar to those of bigger areas such as the North Atlantic. This could be related to higher recruitment levels in the Mediterranean than in the North Atlantic, different reproduction strategies (larger spawning areas in relation to the area of distribution of the stock) and the lower abundance of large pelagic predators (e.g. sharks) in the Mediterranean. Updated information on Mediterranean swordfish catch by gear type is provided in SWO-MED-Table 1 and SWO-MED-Figure 1. The total 2008 catch was 11,153 t (the 2010 assessment reported $12,164 \mathrm{t}$, which included some unofficial estimates), a reduction of about $15 \%$ when compared with 2007 and also with the most recent years. Catch data for 2009 are incomplete. The biggest producers of swordfish in the Mediterranean Sea in recent years are EU-Italy, Morocco, EU-Spain and EUGreece. Also, Algeria, EU-Cyprus, EU-Malta, EU-Portugal, Tunisia and Turkey have fisheries targeting swordfish in the Mediterranean. Minor catches of swordfish have also been reported by Albania, Croatia, EUFrance, Japan, and Libya. The Committee recognized that there may be additional fleets taking swordfish in the Mediterranean, for example, Egypt, Israel, Lebanon, Monaco and Syria, but the data are not reported to ICCAT or FAO.

Mediterranean swordfish landings showed an upward trend from 1965-1972, stabilized between 1973-1977, and then resumed an upward trend reaching a peak in 1988 ( $20,365 \mathrm{t}$; SWO-MED-Table 1, SWO-MED-Figure 1). The sharp increase between 1983 and 1988 may be partially attributed to improvement in the national systems for collecting catch statistics. Since 1988, the reported landings of swordfish in the Mediterranean Sea have declined fluctuating mostly between 12,000 to $16,000 \mathrm{t}$.

The main fishing gears used are surface longline and gillnets. Minor catches are also reported from harpoon, trap and recreational fisheries. Surface longlines are used all over the Mediterranean, while gillnets are still used in some areas and there are also countries known to be fishing with gillnets but not reporting their catches. However, following ICCAT recommendations for a general ban of driftnets in the Mediterranean, the gillnet fleet has been decreasing, although the total number of vessels cannot be determined from ICCAT statistics.

Preliminary results of experimental fishing surveys presented during the 2006 SCRS meeting indicated that selectivity of the surface longline targeting swordfish was more affected by the type and size of the bait, the depth of the set and the distance between branch lines rather than the type (circular vs. J-shaped) and the size of
the hook. In general, American-style longline captures less juvenile fish than the traditional Mediterranean longline gear, while a significant reduction of swordfish catches was found when using circle hooks.

A study based on fisheries data from the eastern Mediterranean presented during the 2009 SCRS suggested that there are no major differences in the age selection pattern among American and traditional longlines and confirmed previous findings regarding the higher catch efficiency of the American gear. It has been noted, however, that further studies in other Mediterranean areas are needed to verify that the estimated selection curves are independent of the stock distribution pattern.

Standardised CPUE series from the main longline and gillnet fisheries targeting swordfish, which were presented during the 2010 stock assessment session (Spanish longliners, Italian longliners, Greek longliners and Moroccan gillnetters), did not reveal any trend over time (SWO-MED-Figure 2). CPUE series, however, covered only the last 10-20 years and not the full time period of reported landings. Similarly to CPUE, not any trend over the past 20 years was identified regarding the mean fish weight in the catches (SWO-MED-Figure 3).

## SWO-MED-3. State of the stocks

Two forms of assessment (production modelling and age-structured analysis-XSA), indicated that current SSB levels are much lower than those in the early 1980s, although not any trend appears in the last 15 years. The extent of the decline differ among models, with the production model suggesting a decline of about $30 \%$, while XSA results indicate that current SSB level is about $1 / 4$ of that in the mid-1980s (SWO-MED-Figure 4). Results indicate that the fishery underwent a rapid expansion in the late 1980s resulting in Fs and catches above those that could support MSY. Estimates of population status from production modeling indicated that current stock level is slightly lower ( $\sim 5 \%$ ) to the optimum needed to achieve the ICCAT Convention objective, but these estimates have a high degree of uncertainty (CV~30\%). Additionally, it should be noted that production model biomass estimates are very sensitive to the assumption made about the initial stock biomass ratio. In general, the low contrast in the available catch-effort series affects the reliability of biomass estimates, as well as, the predictions of effort changes on future catch levels.

Results of yield-per-recruit analyses based on the analytical age-structured assessment in which we have more confidence indicated that the stock is in overfished condition and slight overfishing is taking place. Current (2008) SSB is $46 \%$ lower than the value that would maximize yield per-recruit. Current $F$ is slightly higher to the estimated $\mathrm{F}_{\text {MSY }}$ (SWO-MED-Figure 5). Note, however, that these conclusions are based on deterministic analyses of the available data. The level of uncertainty in these estimates has not been evaluated.

The Committee again noted the large catches of small size swordfish, i.e., less than 3 years old (many of which have probably never spawned) and the relatively low number of large individuals in the catches. Fish less than three years old usually represent $50-70 \%$ of the total yearly catches in terms of numbers and $20-35 \%$ in terms of weight (SWO-MED-Figure 6). A reduction of the volume of juvenile catches would improve yield per recruit and spawning biomass per recruit levels.

## SWO-MED-4. Outlook

The assessment of Mediterranean swordfish indicates that the stock is below the level which can support MSY and that current fishing mortality slightly exceeds $\mathrm{F}_{\text {MSY }}$. Overall results suggest that fishing mortality (and nearterm catches) needs to be reduced to move the stock toward the Convention objective of biomass levels which could support MSY and away from levels which could allow a rapid stock decline. A reduction of current F to the $\mathrm{F}_{0.1}$ level would result to a substantial (about 40\%) long-term increase in SSB (SWO-MED-Figure 7).

Seasonal closure projections based on highly-aggregated data derived from the age-structured assessment and which assume no compensation in effort, no interaction with other management actions in place, and an improvement in recruitment with increasing spawning stock biomass (SSB), are forecast to be beneficial in moving the stock condition closer to the Convention objective, resulting in increased catch levels in the medium term, and reductions in the volume of juvenile catches. Although simulations suggest that the stock can be rebuild to the mid-1980s SSB levels only in the case of six month closures, SSB increases up to the optimum levels suggested by the yield-per-recruit analysis can be achieved within 2-3 generations (8-12 years) even under the current management status (2-month closure), provided that fishing mortality is kept on 2008 levels, which
were quite lower than the previous years. Risk analysis, however, indicates that a small probability ( $<5 \%$ ) of stock collapse still exists in this case. Benefits from seasonal closures would be diminished if closure is applied in months of low fishing activity (December-January). It should be noted that seasonal closures, especially the longer ones, would result in significant catch reductions within the first few years after their application. Capacity reductions of $20 \%$ assuming no compensation in effort, or quotas equal to the $80 \%$ of the mean yield of the last decade assuming no change in the selection pattern, could also result to stock rebuilt to optimum SSB levels. Results of the seasonal closure projections are summarized in SWO-MED-Figure 8.

## SWO-MED-5. Effects of current regulations

ICCAT imposed a Mediterranean-wide one month fishery closure for all gears targeting swordfish in 2008, followed by a two-month closure since 2009. Several countries have imposed technical measures, such as closed areas and seasons, minimum landing size regulations and license control systems. The EU introduced a driftnet ban in 2002 and in 2003 ICCAT adopted a recommendation for a general ban of this gear in the Mediterranean [Rec. 03-04]. Rec. 04-12 forbids the use of various types of nets and longlines for sport and recreational fishing for tuna and tuna-like species in the Mediterranean.

In past meetings, the Committee has reviewed the various measures taken by Contracting Parties and noted the difficulties in implementing some of the management measures, particularly that of minimum landing size.

## SWO-MED-6. Management recommendations

The Commission should adopt a Mediterranean swordfish fishery management plan which ensures that the stock will be rebuilt and kept in levels that are consistent with the ICCAT Convention objective. Given the uncertainties on optimum SSB level estimates and the rapid fishery expansion in the 1980s, which resulted in severe stock biomass declines, the SSB levels in the late 1980s may be also considered as a good proxy for the stock. These levels, are around to $60,000-70,000$ t, not very far, however, from the currently estimated $\mathrm{B}_{\text {MSY }}$ value ( $\sim 62000 \mathrm{t}$ ). Analysis has suggested that the seasonal closures have beneficial effects and can move the stock condition to the level which will support MSY, but the effect of the recently employed two-month closure could not be evaluated due to incomplete 2009 data.

Following the results from recent studies (SCRS/2006/163), technical modifications of the longline fishing gears, as well as, the way they are operated can be considered as an additional technical measure in order to reduce the catch of juveniles. The Committee recommends this type of measures be considered as part of a Mediterranean swordfish management plan. Given that the current capacity in the Mediterranean swordfish fishery exceeds that needed to efficiently extract MSY, management measures aimed at reducing this capacity should also be considered part of a Mediterranean swordfish management plan adopted by the Commission.

## MEDITERRANEAN SWORDFISH SUMMARY

| Maximum Sustainable Yield | $\sim 14,600^{1}$ |
| :--- | :--- |
| Current (2008) Yield ${ }^{2}$ | $12,164 \mathrm{t}$ |
| Current (2008) Replacement Yield | $\sim 12,100 \mathrm{t}^{1}$ |
| Relative Biomass ( $\mathrm{B}_{2008} / \mathrm{B}_{\mathrm{MSY}}$ ) | $0.54^{1}$ |
| Relative Fishing Mortality |  |
| $\mathrm{F}_{2008} / \mathrm{F}_{\text {MSY }}$ | $1.03^{1}$ |
| $\mathrm{~F}_{2008} / \mathrm{F}_{\text {MAX }}$ | $0.91^{1}$ |
| $\mathrm{~F}_{2008} / \mathrm{F}_{0.1}$ | $1.52^{1}$ |
| $\mathrm{~F}_{2008} / \mathrm{F}_{30 \% \mathrm{SPR}}$ | $1.32^{1}$ |
| Management measures in effect | Driftnet ban [Rec. 03-04] |
|  | Two month fishery closure ${ }^{3}$ |
| ${ }^{1}$ Based on the age-structured analysis. |  |
| ${ }^{2}$ The 2009 reported catch is considered incomplete and too provisional to use in this table. |  |
| ${ }^{3}$ Various technical measures, such as closed areas, minimum size regulations and effort controls are implemented at the national level. |  |

SWO-MED-Table 1. Estimated catches (t) of swordfish (Xiphias gladius) in the Mediterranean by gear and flag, used in the assessment (2009 catches in Italic are estimations adopted by the WG)

### 8.10 SBF - SOUTHERN BLUEFIN TUNA

The Commission for the Conservation of Southern Bluefin Tuna (CCSBT) is charged with assessing the status of southern bluefin tuna. Each year, SCRS reviews the CCSBT reports to learn about southern bluefin research and stock assessments. These reports are available from CCSBT.

### 8.11 SMT - SMALL TUNAS

## SMT-1. Generalities

Small tunas include the following species:

```
- BLF Blackfin tuna (Thunnus atlanticus)
- BLT Bullet tuna (Auxis rochei)
- BON Atlantic bonito (Sarda sarda)
- BOP Plain bonito (Orcynopsis unicolor)
- BRS Serra Spanish mackerel (Scomberomorus brasiliensis)
- CER Cero (Scomberomorus regalis)
- FRI Frigate tuna (Auxis thazard)
- KGM King mackerel (Scomberomorus cavalla)
- KGX Scomberomorus unclassified (Scomberomorus spp.)
- LTA Little tunny (Euthynnus alletteratus)
- MAW West African Spanish mackerel (Scomberomorus tritor)
- SSM Atlantic Spanish mackerel (Scomberomorus maculatus)
- WAH Wahoo (Acanthocybium solandri)
```

Knowledge on the biology and fishery of small tunas is very fragmented in several areas. Furthermore, the quality of the knowledge is very different according to the species concerned. This is due in large part because many of these species are often perceived to have little economic importance compared to other tuna and tunalike species, and owing to the difficulties in conducting sampling of the landings from artisanal fisheries, which constitute a high proportion of the fisheries exploiting small tuna resources. The large industrial fleets often discard small tuna catches at sea or sell them on local markets mixed with other by-catches, especially in Africa (SCRS/2009/147). The amount caught is rarely reported in logbooks; however observer programs from purse seine fleets have recently provided estimates of catches of small tunas (SCRS/2009/146).

Small tuna species have a very high relevance from a socio-economic point of view, because they are important for many coastal communities in all areas and are a main source of food. The socio-economic value is often not evident because of the underestimation of the total figures, due to the above mentioned difficulties in data collection. Several statistical problems are also caused by misidentification and some of them were faced and discussed during this Small Tunas Species Group meeting. The small tuna species can reach high levels of catches and value in some years.

Scientific collaboration among ICCAT, RFOs and countries in the various regions is imperative to advance understanding of the distribution, biology and fishery of these species.

## SMT-2. Biology

These species are widely distributed in the tropical and subtropical waters of the Atlantic Ocean and several are also distributed in the Mediterranean Sea and the Black Sea. Some species extend their range even to colder waters, like the North and South Atlantic Ocean. They often form large schools with other small sized tunas or related species in coastal and high seas waters.

Generally, the small tuna species have a varied diet with a preference for small pelagics (e.g., clupeids, mullets, carangids, etc.), crustaceans, mollusks and cephalopods. Many of these species are also prey of large tunas, marlins and sharks. The reproduction period varies according to species and spawning generally takes place near the coast in oceanic areas, where the waters are warmer. The growth rate currently estimated for these species is very rapid for the first two or three years, and then slows as these species reach size-at-first maturity. Studies about the migration patterns of small tuna species are very rarely available, due to the practical difficulties in manipulating and tagging these species.

New information regarding the reproductive biology of Atlantic bonito (Sarda sarda) and wahoo (Acanthocybium solandri) was submitted to the Group. In addition, information regarding wahoo and slender tuna (Allothunnus fallai) as by-catch species of the Brazilian longline fishery and Brazilian artisanal beach seine fishery, respectively, was also reported.

Although there is a general lack of information on biological parameters for these species, the need for information is especially critical for West Africa and the Caribbean and South America.

The small tuna species identification sheets have already been completed and are available from the Secretariat.

## SMT-3. Description of the fisheries

Small tunas are exploited mainly by coastal fisheries and artisanal fisheries, although substantial catches are also made as target species and as by-catch by purse seine, mid-water trawlers (i.e., pelagic fisheries of West AfricaMauritania), handline and small scale gillnets. Unknown quantities of small tuna also comprise the incidental catches of some longline fisheries. The increasing importance of FAD fisheries in the eastern Caribbean and in other areas has improved the efficiency of artisanal fisheries in catching small tunas. Various species are also caught by the sport and recreational fisheries.

Despite of the scarce monitoring of various fishing activities in some areas, all the small tuna fisheries have a high socio-economic relevance for most of the coastal countries concerned and for many local communities, particularly in the Mediterranean Sea, in the Caribbean region and in West Africa.

SMT-Table 1 shows historical landings of small tunas for the 1980 to 2009 period although data for last year are preliminary. This table does not include species reported as "mixed" or "unidentified", as was the case in previous years, since these categories include large tuna species. There are more than 10 species of small tunas, but only five of these account for about $88 \%$ of the total reported catch by weight. These five species are: Atlantic bonito (Sarda sarda), frigate tuna (Auxis thazard) which may include some catches of bullet tuna (Auxis rochei), little tunny (Euthynnus alletteratus), king mackerel (Scomberomorus cavalla), and Atlantic Spanish mackerel (Scomberomorus maculatus) (SMT-Figure 2). In 1980, there was a marked increase in reported landings compared to previous years, reaching a peak of about 147,202 t in 1988 (SMT-Figure 1). Reported landings for the 1989-1995 period decreased to approximately $91,907 \mathrm{t}$, and then an oscillation in the values in the following years, with a minimum of $72,460 \mathrm{t}$ in 2003 and a maximum of 129,353 t in 2005. Overall trends in the small tuna catch may mask declining trends for individual species because annual landings are often dominated by the landings of a single species. These fluctuations seem to be related to unreported catches, as these species generally comprise part of the by-catch and are often discarded, and therefore do not reflect the real catch.

A preliminary estimate of the total nominal landings of small tunas in 2009 is $50,873 \mathrm{t}$. The Small Tunas Species Group pointed out the relative importance of small tuna fisheries in the Mediterranean and the Black Sea, which account for about 28\% of the total reported catch in the ICCAT area for the period 1980-2008.

Despite the recent improvements in the statistical information provided to ICCAT by several countries, either with the provision of Task I data or with information provided by national scientists during the Small Tunas Species Group meeting, the Committee also noted that uncertainties remain regarding the accuracy and completeness of reported landings in all areas. There is a general lack of information on the mortality of these species as by-catch, exacerbated by the confusion regarding species identification.

## SMT-4. State of the stocks

There is little information available to determine the stock structure of many small tuna species. The Committee suggests that countries be requested to submit all available data to ICCAT as soon as possible, in order to be used in future meetings of the Committee.

Generally, current information does not allow the Committee to carry out an assessment of stock status of the majority of the species. Some analyses will be possible in future if data availability improves with the same trend of the latest year. Nevertheless, few regional assessments have been carried out. Assessments of stocks of small tunas are also important because of their position in the trophic chain where they are the prey of large tunas, marlins and sharks and they are predators of smaller pelagic. It may therefore be best to approach assessments of small tunas from the ecosystem perspective.

## SMT-5. Outlook

There is an improvement in the availability of catch and biological data for small tuna species particularly in the Mediterranean and the Black Sea. However, biological information, catch and effort statistics for small tunas remain incomplete for many of the coastal and industrial fishing countries. Given that, many of these species are of high importance to coastal fishermen, especially in some developing countries, both economically and often as a primary source of protein, therefore the Committee recommends that further studies be conducted on small tuna species due to the small amount of information available.

## SMT-6. Effects of current regulations

There are no ICCAT regulations in effect for small tunas. Several regional and national regulations are in place.

## SMT-7. Management recommendations

No management recommendations have been made.

SMT-Table 1. Reported landings ( t ) of small tuna species, by area and flag.

### 8.12 SHK - SHARKS

In response to the Supplemental Recommendation by ICCAT Concerning the Conservation of Sharks Caught in Association with Fisheries Managed by ICCAT [Rec. 06-10], an updated assessment of the stocks of blue shark (Prionace glauca) and shortfin mako (Isurus oxyrinchus) was conducted in 2008. Ecological risk assessments (ERA) were also conducted for nine additional priority species of pelagic elasmobranchs, for which available data are very limited (Isurus paucus, Alopias superciliosus, Alopias vulpinus, Carcharhinus longimanus, C. falciformis, Lamna nasus, Sphyrna lewini, Sphyrna zygaena, and Pteroplatytrygon violacea). In 2009, an assessment of porbeagle stocks was conducted jointly with ICES, in response to the Resolution by ICCAT on Porbeagle Shark [Rec. 08-08].

The quantity and quality of the data available (e.g., historical catches and CPUE information) to conduct stock assessments have increased with respect to those available in the first (2004) shark assessments (Anon. 2005c) conducted by ICCAT. However, they are still quite uninformative and do not provide a consistent signal to inform the assessment. Unless these and other issues can be resolved, the assessments of stock status for all pelagic shark species will continue to be very uncertain and our ability to detect stock depletion to levels below the Convention Objective level will remain considerably low.

A summary of the Committee's findings based on the 2008 (Anon. 2009c) and 2009 (SCRS/2009/014) assessment results is presented below. Although pelagic sharks are captured in the Atlantic Ocean with a wide variety of fishing gears, the largest volume of most of the species of major concern to ICCAT are captured by pelagic longline fisheries.

The Committee assessed blue and shortfin mako sharks in 2008 assuming the existence of three separate stocks: North, South and Mediterranean. However, the data available to the Committee for the Mediterranean were not considered sufficient to conduct quantitative assessments for these species. The assessment results presented high levels of uncertainty due to data limitations. Similarly, the Committee assessed in 2009 porbeagle sharks assuming the existence of four separate stocks: Northwest, Northeast (including the Mediterranean, for which only limited information is available), Southwest and Southeast. The assessment results for the southern porbeagle stocks also presented high levels of uncertainty due to data limitations.

Increased research and data collection are required to enable the Committee to improve the advice it can offer.

## SHK-1. Biology

A great variety of shark species are found within the ICCAT Convention area, from coastal to oceanic species. Biological strategies of these sharks are very diverse and are adapted to the needs within their respective ecosystems where they occupy a very high position in the trophic chain as active predators. Therefore, generalization as regards to the biology of these very diverse species results in inevitable inaccuracies, as would occur for teleosts. To date, ICCAT has prioritized the biological study and assessment of the major sharks of the epipelagic system as these species are more susceptible of being caught as by-catch by oceanic fleets targeting tuna and tuna-like species. Among these shark species there are some of special prevalence and with an extensive geographical distribution within the oceanic-epipelagic ecosystem, such as the blue shark and shortfin mako shark, and others with less or even limited prevalence, such as porbeagle, hammerhead sharks, thresher sharks, white sharks, etc.

Blue shark and shortfin mako sharks show a wide geographical distribution, most often between $50^{\circ} \mathrm{N}$ and $50^{\circ} \mathrm{S}$ latitude. On the contrary, porbeagle show a distribution that is restricted to cold-temperate waters, preferably close to the continental shelf of both hemispheres where this species rarely overlaps with the fishing activity directed at tunas and tuna-like species. These three species have an ovoviviparous reproductive strategy, which increases the probability of survival of their young, with litters from only a few individuals in the case of shortfin mako and porbeagle, to abundant litters of about 40 pups in the case of blue shark. Their growth rates differ between sexes and among these three species. Females often reach first maturity at a large size. A characteristic of these species is usually their tendency to segregate temporally and spatially by size-sex, according to their respective processes of feeding, mating-reproduction, gestation and birth. Numerous aspects of the biology of these species are still poorly understood or completely unknown, particularly for some regions, which contributes to increased uncertainty in quantitative and qualitative assessments.

## SHK-2. Fishery indicators

Earlier reviews of the shark database resulted in recommendations to improve data reporting on shark catches. Though global statistics on shark catches included in the database have improved, they are still insufficient to permit the Committee to provide quantitative advice on stock status with sufficient precision to guide fishery management toward optimal harvest levels. Reported catches for blue shark, shortfin mako and porbeagle are provided in SHK-Table 1. Given that catch reports to ICCAT are incomplete, the Committee attempted to develop a more accurate estimate of shark mortality and capture related to the Atlantic tuna fleets on the basis of the expected proportions among tunas and sharks and in the landings of these fleets (SHK-Figure 1 to 4) as well as using shark fin trade data. These information sets were used to reconstruct plausible estimates of historic catches used in blue shark and shortfin mako assessments in 2008 and porbeagle in 2009.

A number of standardized CPUE data series for blue shark and shortfin mako were presented in 2008 as relative indices of abundance. The Committee placed emphasis on using the series that pertained to fisheries that operate in oceanic waters over wide areas. SHK-Figure 5 presents the central tendency of the available series for the four stocks of these species.

Considering the quantitative and qualitative limitations of the information available to the Committee, the results presented in 2008, as those of the 2004 assessment (Anon. 2005c), are not conclusive. During the porbeagle assessment in 2009 (SCRS/2009/014), standardized CPUE data were presented for three of the four stocks (NE, NW and SW; SHK-Figure 6). These series when referring to fisheries targeting porbeagle could fail to reflect the global abundance of the stock and where they refer to sharks caught as by-catch they could be highly variable.

With regard to the species for which ERAs were conducted, the Committee understands that, in spite of existing uncertainties, results make it possible to identify those species that are more susceptible and vulnerable (based only on productivity) to prioritize research and management measures (SHK-Table 2). These ERAs are conditional on the biological variables used to estimate productivity as well as the susceptibility values for the different fleets and thus may change in the future as new information becomes available.

## SHK-3. State of the Stocks

Ecological risk assessments for eleven priority species of sharks (including blue shark and shortfin mako) caught in ICCAT fisheries demonstrated that most Atlantic pelagic sharks have exceptionally limited biological productivity and, as such, can be overfished even at very low levels of fishing mortality. Specifically, the analyses indicated that bigeye threshers, longfin makos, and shortfin makos have the highest vulnerability (and lowest biological productivity) of the shark species examined (with bigeye thresher being substantially less productive than the other species). All species considered in the ERA, particularly smooth hammerhead, longfin mako, bigeye thresher and crocodile sharks, are in need of improved biological data to evaluate their biological productivity more accurately and thus specific research projects should be supported to that end. SHK-Table 2 provides a productivity ranking of the species considered. ERAs should be updated with improved information on the productivity and susceptibility of these species.

## SHK-3.1 Blue shark

For both North and South Atlantic blue shark stocks, although the results are highly uncertain, biomass is believed to be above the biomass that would support MSY and current harvest levels below F $\mathrm{F}_{\text {MSY }}$. Results from all models used in the 2008 assessment (Anon. 2009c) were conditional on the assumptions made (e.g., estimates of historical catches and effort, the relationship between catch rates and abundance, the initial state of the stock in the 1950s, and various life-history parameters), and a full evaluation of the sensitivity of results to these assumptions was not possible during the assessment. Nonetheless, as for the 2004 stock assessment (Anon. 2005c), the weight of available evidence does not support hypotheses that fishing has yet resulted in depletion to levels below the Convention objective (SHK-Figure 7).

## SHK-3.2 Shortfin mako shark

Estimates of stock status for the North Atlantic shortfin mako obtained with the different modeling approaches applied in 2008 were much more variable than for blue shark. For the North Atlantic, most model outcomes indicated stock depletion to about $50 \%$ of biomass estimated for the 1950 s. Some model outcomes indicated that
the stock biomass was near or below the biomass that would support MSY with current harvest levels above $\mathrm{F}_{\mathrm{MSY}}$, whereas others estimated considerably lower levels of depletion and no overfishing (SHK-Figure 7). In light of the biological information that indicates the point at which $\mathrm{B}_{\mathrm{MSY}}$ is reached with respect of the carrying capacity which occurs at levels higher than for blue sharks and many teleost stocks. There is a non-negligible probability that the North Atlantic shortfin mako stock could be below the biomass that could support MSY. A similar conclusion was reached by the Committee in 2004, and recent biological data show decreased productivity for this species. Only one modeling approach could be applied to the South Atlantic shortfin mako stock, which resulted in an estimate of unfished biomass which was biologically implausible, and thus the Committee can draw no conclusions about the status of the South stock.

## SHK-3.3 Porbeagle shark

In 2009, the Committee attempted an assessment of the four porbeagle stocks in the Atlantic Ocean: Northwest, Northeast, Southwest and Southeast. In general, data for southern hemisphere porbeagle are too limited to provide a robust indication on the status of the stocks. For the Southwest, limited data indicate a decline in CPUE in the Uruguayan fleet, with models suggesting a potential decline in porbeagle abundance to levels below MSY and fishing mortality rates above those producing MSY (SHK-Figure 8). But catch and other data are generally too limited to allow definition of sustainable harvest levels. Catch reconstruction indicates that reported landings grossly underestimate actual landings. For the Southeast, information and data are too limited to assess their status. Available catch rate patterns suggest stability since the early 1990s, but this trend cannot be viewed in a longer term context and thus are not informative on current levels relative to $\mathrm{B}_{\text {MSY }}$.

The northeast Atlantic stock has the longest history of commercial exploitation. A lack of CPUE data for the peak of the fishery adds considerable uncertainty in identifying the current status relative to virgin biomass. Exploratory assessments indicate that current biomass is below $\mathrm{B}_{\mathrm{MSY}}$ and that recent fishing mortality is near or above $\mathrm{F}_{\text {MSY }}$ (SHK-Figure 9). Recovery of this stock to $\mathrm{B}_{\text {MSY }}$ under no fishing mortality is estimated to take ca. 15-34 years. The current EU TAC of 436 t in effect for the Northeast Atlantic may allow the stock to remain stable, at its current depleted biomass level, under most credible model scenarios. Catches close to the current TAC (e.g. 400 t ) could allow rebuilding to $\mathrm{B}_{\text {MSY }}$ under some model scenarios, but with a high degree of uncertainty and on a time scale of $60(40-124)$ years.

An update of the Canadian assessment of the northwest Atlantic porbeagle stock indicated that biomass is depleted to well below $\mathrm{B}_{\text {MSY }}$, but recent fishing mortality is below $\mathrm{F}_{\text {MSY }}$ and recent biomass appears to be increasing. Additional modelling using a surplus production approach indicated a similar view of stock status, i.e., depletion to levels below $\mathrm{B}_{\text {MSY }}$ and current fishing mortality rates also below $\mathrm{F}_{\text {MSY }}$ (SHK-Figure 10). The Canadian assessment projected that with no fishing mortality, the stock could rebuild to $\mathrm{B}_{\text {MSY }}$ level in approximately 20-60 years, whereas surplus-production based projections indicated 20 years would suffice. Under the Canadian strategy of a $4 \%$ exploitation rate, the stock is expected to recover in 30 to $100+$ years according to the Canadian projections.

## SHK-4. Management Recommendations

Precautionary management measures should be considered for stocks where there is the greatest biological vulnerability and conservation concern, and for which there are very few data. Management measures should ideally be species-specific whenever possible.

For species of high concern (in terms of overfishing), and for which a high survivorship is expected in fishing gears after release, the Committee recommends that the Commission prohibits retention and landings of the species to minimize fishing mortality. The Committee recognizes that the difficulty in identifying look-alike species may complicate compliance with management measures adopted for those species

For all the species, but particularly for those which can be easily misidentified, it is essential that the Committee advances data collection, and research on life history, together with the interactions with tuna fisheries, with the final objective of assessing the status of the stocks. Until such information is made available, the Commission should consider taking effective measures to reduce the fishing mortality of these stocks. These measures may include minimum or maximum size limits for landing (for protection of juveniles or the breeding stock, respectively); and any other technical mitigation measures such as gear modifications, time-area restrictions, or others as appropriate. Such management actions should be combined with research activities, in order to provide information of their effectiveness.

Both porbeagle stocks in the NW and NE Atlantic were estimated to be overfished, with the northeastern stock being more highly depleted. The main source of fishing mortality on these stocks is from directed porbeagle fisheries which are not under the Commission's direct mandate. Those fisheries are managed mostly by ICCAT Contracting Parties through national legislation which include quotas and other management measures.

The Committee also recommends that countries initiate research projects to investigate means to minimize bycatch and discard mortality of sharks, with a particular view to recommending to the Commission complementary measures to minimize porbeagle by-catch in fisheries for tuna and tuna-like species. For porbeagle sharks, the Committee recommends that the Commission work with countries catching porbeagle, particularly those with targeted fisheries, and relevant RFMOs to ensure recovery of North Atlantic porbeagle stocks and prevent overexploitation of South Atlantic stocks. In particular, porbeagle fishing mortality should be kept to levels in line with scientific advice and with catches not exceeding current level. New targeted porbeagle fisheries should be prevented, porbeagles retrieved alive should be released alive, and all catches should be reported. Management measures and data collection should be harmonized as much as possible among all relevant RFMOs dealing with these stocks, ICCAT should facilitate appropriate communication.

The Committee recommends that joint work with the ICES Working Group on Elasmobranch Fishes should be continued. In light of the changing methods in the provision of ICES advice, from the Precautionary Approach to $\mathrm{F}_{\mathrm{MSY}}$, the 2009 joint ICCAT/ICES porbeagle (Lamna nasus) assessment should be revisited. Representatives of the Committee should attend the 2011 WGEF meeting (Copenhagen, June 2011), to update the NE Atlantic porbeagle assessment with recent data, in preparation for a full assessment in 2012. In addition, stocks of mutual interest and areas of overlap, particularly species occurring in the Mediterranean Sea, should be discussed.

Considering that (a) the oceanic whitetip shark (Carcharhinus longimanus), as in the case of bigeye thresher (Alopias superciliosus), has been ranked as one of the five species with the highest degree of risk in an ecological risk assessment performed by the SCRS in 2008 for sharks, due to the lack of the provision of data; (b) that it has high at-vessel survival and constitutes a small portion of the shark catch; (c) that it is one of the easiest shark species to identify, particularly by their characteristic fins; and (d) that a significant proportion of the species catch is composed of juvenile individuals; the group recommends invocation of a precautionary approach in suggesting a minimum size in total length be established for the species. Therefore, the Committee recommends the adoption of a minimum size of 200 cm total length which would allow protection of the first reproductive ages. The Committee further recommends that research be conducted to better determine what life stages are more important for the productivity of the stock.

The Committee should conduct a Data Preparatory Meeting in 2011 with the purpose of generating a larger and better database to update in 2012 the Ecological Risk Assessment conducted in 2008. To that end, national scientists should assemble and present all available information on fisheries operations and pelagic shark life history. Of special interest is any information on fisheries operations gathered by national observer programs related to overlap of fisheries with geographic distribution of pelagic sharks, overlap of gear with vertical distribution of individual species (particularly information collected with satellite tags), as well as status, disposition and size of animals brought to the vessel.

## NORTH ATLANTIC BLUE SHARK SUMMARY

| 2007 Yield |  | $61,845 \mathrm{t}^{1}$ |
| :--- | :--- | :--- |
| Provisional Yield (2009) |  | $33,208 \mathrm{t}^{2}$ |
| Relative Biomass: | $\mathrm{B}_{2007} / \mathrm{B}_{\mathrm{MSY}}$ | $1.87-2.74^{3}$ |
|  | $\mathrm{~B}_{2007} / \mathrm{B}_{0}$ | $0.67-0.93^{4}$ |
| Relative Fishing Mortality: | $\mathrm{F}_{\text {MSY }}$ | $0.15^{5}$ |
|  | $\mathrm{~F}_{2007} / \mathrm{F}_{\mathrm{MSY}}$ | $0.13-0.17^{6}$ |

[^7]
## SOUTH ATLANTIC BLUE SHARK SUMMARY

2007 Yield
Provisional Yield (2009)
Relative Biomass:
Relative Fishing Mortality:

|  | $37,075 \mathrm{t}^{1}$ |
| :--- | :--- |
|  | $22,439 \mathrm{t}^{2}$ |
|  | $1.95-2.80^{3}$ |
| $\mathrm{~B}_{2007} / \mathrm{B}_{\mathrm{MSY}}$ | $0.86-0.98^{4}$ |
| $\mathrm{~B}_{2007} / \mathrm{B}_{0}$ | $0.15-0.20^{5}$ |
| $\mathrm{~F}_{\text {MSY }}$ | $0.04-0.09^{6}$ |

${ }^{1}$ Estimated catch used in the 2008 assessments.
${ }^{2}$ Task I catch.
${ }^{3}$ Range obtained from BSP (low) and CFASP (high) models. Value from CFASP is SSB/SSB ${ }_{\text {MSY }}$
${ }^{4}$ Range obtained from BSP (high) and CFASP (low) models. Value from CFASP is SSB/SS ${ }_{B 0}$.
${ }^{5}$ Range obtained from BSP (low) and CFASP (high) models.
${ }^{6}$ Range obtained from BSP (low) and CFASP (high) models.

## NORTH ATLANTIC SHORTFIN MAKO SUMMARY

## 2007 Yield

Provisional Yield (2009)
Relative Biomass:
Relative Fishing Mortality:
Management measures in effect
${ }^{1}$ Estimated catch used in the 2008 assessments.
${ }^{2}$ Task I catch.
${ }^{3}$ Range obtained from BSP (low) and CFASP (high) models. Value from CFASP is SSB/SSB ${ }_{\text {MSY. }}$
${ }_{5}^{4}$ Range obtained from BSP (low), AS, and CFASP (high) models. Value from CFASP is SSB/SS ${ }_{B 0}$.
${ }^{5}$ Range obtained from BSP (low) and CFASP (high) models.
${ }^{6}$ Range obtained from BSP (high) and CFASP (low) models.

## NORTHWEST ATLANTIC PORBEAGLE SUMMARY

Current Yield (2008)

## Relative Biomass:

Relative Fishing Mortality:
Management measures in effect
$144.3 \mathrm{t}^{1}$
$\begin{array}{ll}\mathrm{B}_{2008} / \mathrm{B}_{\text {MSY }} & 0.43-0.65^{2} \\ \mathrm{~F}_{\text {MSY }} & 0.025-0.075^{3} \\ \mathrm{~F}_{2008} / \mathrm{F}_{\text {MSY }} & 0.03-0.36^{4}\end{array}$
TAC of 185, $11.3 \mathrm{t}^{5}$

[^8]
## SOUTHWEST ATLANTIC PORBEAGLE SUMMARY

Current Yield (2008)
$164.6 \mathrm{t}^{1}$
Relative Biomass:
$\mathrm{B}_{2008} / \mathrm{B}_{\mathrm{MSY}}$
$0.36-0.78^{2}$
Relative Fishing Mortality:
Management measures in effect
$\mathrm{F}_{\mathrm{MSY}}$
$\mathrm{F}_{2008} / \mathrm{F}_{\mathrm{MSY}}$
$0.025-0.033^{3}$
$0.31-10.78^{4}$
None
${ }^{1}$ Estimated catch allocated to the Southwest stock area.
${ }^{2}$ Range obtained from BSP (low and high) and CFASP models. Value from CFASP model (SSB/SSB ${ }_{\text {MSY }}$ ) was 0.48 (0.20).
${ }^{3}$ Range obtained from BSP (low) and CFASP (high) models.
${ }^{4}$ Range obtained from BSP (low and high) and CFASP models. Value from CFASP model was 1.72 (0.51).

## NORTHEAST ATLANTIC PORBEAGLE SUMMARY

Current Yield (2008)
Relative Biomass:
Relative Fishing Mortality:
Management measures in effect
$287 \mathrm{t}^{1}$
$\mathrm{B}_{2008} / \mathrm{B}_{\mathrm{MSY}}$
$\mathrm{F}_{\mathrm{MSY}}$
$\mathrm{F}_{2008} / \mathrm{F}_{\mathrm{MSY}}$
$0.09-1.93^{2}$
$0.02-0.03^{3}$
$0.04-3.45^{4}$

TAC of $436 \mathrm{t}^{5}$
Maximum landing length of $210 \mathrm{~cm} \mathrm{FL}^{5}$

SHK-Table 2. Productivity values ranked from lowest to highest.

| Species | Productivity $(r)$ | Productivity rank |
| :--- | :---: | :---: |
| BTH (Alopias superciliosus) | 0.010 | 1 |
| SMA (Isurus oxyrinchus) | 0.014 | 2 |
| LMA (Isurus paucus) | 0.014 | 3 |
| POR (Lamna nasus) | 0.053 | 4 |
| FAL (Carcharhinus falciformis) | 0.076 | 6 |
| OCS (Carcharhinus longimanus) | 0.087 | 7 |
| SPL (Sphyrna lewini) | 0.090 | 8 |
| SPZ (Sphyrna zygaena) | 0.124 | 9 |
| ALV (Alopias vulpinus) | 0.141 | 10 |
| PST (Pteroplatytrygon violacea) | 0.169 | 11 |
| BSH (Prionace glauca) | 0.301 | 12 |
| CRO (Pseudocarcharias kamoharai) | - | - |

SHK-Figure 1. Blue shark and shortfin mako catches reported to ICCAT and estimated by the Committee.

SHK-Figure 2. Potential catch of porbeagle by non-reporting longline fleets using catch ratios for the NW stock. Limited observations across the time-series result in an unquantified uncertainty in the estimates.

SHK Figure 3. Left plate: Estimated catch of porbeagle by non-reporting longline fleets using catch ratios for the SW stock. Very limited observations across the time-series result in a high but unquantified uncertainty in the estimates. Right plate: Comparison of estimates for non-reporting longline fleets with reported catch levels held in the Task I data set for the SW stock area.

SHK Figure 4. Catch by flag of porbeagle sharks from the northeastern Atlantic used in the assessment. While these catches are considered the best available,, they are believed to underestimate the pelagic longline catches for this species.

SHK-Figure 5. Average trends in the CPUE series used in the assessments of blue shark (BSH) and shortfin mako (SMA). The averages were calculated by weighting the available series either by their relative catch or by the relative spatial coverage of the respective fisheries.

SHK-Figure 6. CPUE series for the porbeagle NW stock (upper figures), NE stock (lower left figures) and SW stock (lower right figure).

SHK-Figure 7. Phase plots summarizing base scenario outputs for the current stock status of blue shark (BSH) and shortfin mako (SMA). BSP=Bayesian surplus production model; CFASPM=catch-free, age-structured production model. The shaded box represents the area at which the biomass at MSY is estimated to be reached. Any points inside or to the left of the box indicate the stock is overfished (with respect to biomass). Any points above the horizontal line indicate overfishing (with respect to F ) is occurring.

SHK-Figure 8. Phase plot for the southwest Atlantic porbeagle, showing status in 2009 from both the BSP model runs (diamonds) and the catch free age structured production model (square) results. Error bars are plus and minus one standard deviation.

SHK-Figure 9. Phase plot showing current status of northeast Atlantic porbeagle for the BSP model (diamonds) and the ASPM model (squares). Error bars are plus and minus one standard deviation.

SHK-Figure 10. Phase plot showing the northwest Atlantic porbeagle expected value of $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ in the current year, which is either 2005 (diamonds) or 2009 (circles), as well as approximate values from SCRS/2009/095 (squares). B/B MSY was approximated from SCRS/2009/095 as N2009/N1961 times 2. Error bars are plus and minus one standard deviation.

## 9. Report of inter-sessional meetings

The reports of the inter-sessional meetings held in 2010 were presented, with special emphasis not directly related to the stock assessments because their results are not included and presented in the Executive Summaries. The following meetings were presented.

### 9.1 Working Group on Stock Assessment Methods

The main term of reference of the Working Group was to advise the Commission how the precautionary approach could be best expressed in the ICCAT Convention. As well as suggesting changes to the Convention text in order to incorporate the precautionary approach the Group recommended harmonisation of estimation procedures and produced guidelines for the application of the Kobe II strategy matrix. It was recommended that all Species Groups construct a Kobe II Strategy Matrix (K2SM) and should clearly document how the matrix was constructed.

## Discussion

The subsequent discussion recognised the importance of socio-economics although it was also noted that the capacity within the SCRS for this type of work still lagged behind that for stock assessment. In response to a Recommendation related to simulation testing of methods used for standardisation of CPUE the importance of understanding the operational changes in fisheries over time was emphasised.

Document SCRS/2010/010 contains the detailed report of the meeting.

### 9.2 Bigeye Data Preparatory Meeting

The Tropical Tuna Working group met two months before the assessment to prepare the data necessary for the population analyses. The meeting had the dual purpose of preparing the general basic fishery data, such as estimates of total harvest and relative abundance estimates, and the highly specific data required to support the use of statistically-based age-structured population models (Multifan-CL and SS3). The later require far more time for preparation of inputs than the VPA and production models, time that would not have been available during the assessment meeting.

The data preparatory meeting achieved its main goals: in addition to obtaining estimates of harvest the majority of the data required for inputs for statistically-based age-structured population models was developed during the data preparatory meeting.

The detailed report of the meeting is presented as document SCRS/2010/011.

## Discussion

The SCRS acknowledges the comprehensive analyses and presentation regarding the bigeye evaluation during 2010. It was noted, that the use of multiple models for evaluation provides a better view of the levels of uncertainty of the overall assessment. The Chair of the Working Group reflected on the advantages and limitations of having a data preparatory meeting and an assessment meeting. It was noted that the implementation of complex models such Catch Statistical Models require a large effort in data preparation and integration between scientist and the Secretariat, as well sufficient time to run alternative models which are not possible in a single meeting.

### 9.3 Blue Marlin Data Preparatory Meeting

A Blue marlin Data Preparatory Meeting was held in Madrid, May 17 to 21, 2010 to review and update basic information, review and compile new biological and habitat information, review catch reports, and update relative abundance indices for Atlantic blue marlin. Analysis of basic information (T1NC, T1FC, T2CE, and T2SZ) was carried out by the Working Group, revisions and new data reported during the meeting were incorporated into the ICCAT database. Size information was analyzed in detail for its potential use in integrated assessment models and its potential for a future creation of a catch-at-size/age estimation to be used in structured type models. New information on the estimation of age structure and growth of blue marlin was presented. In addition, a new research on the impact of the oxygen minimum zone (OMZ) in the eastern tropical Atlantic on the vertical habitat use of blue marlin provided new insights on its vulnerability to surface gears and the potential
variation in catchability inside and outside the OMZ. Analysis of reported catches generated new estimates of total catch for the stock. These analyses included disaggregation of catches reported such as unclassified billfish and filling the gaps of the time series for fleets that had incomplete historical reports. Several relative abundance indices were presented at the meeting including updates of the Brazilian longline, United States recreational and longline, and Venezuelan small scale, longline, and recreational fisheries; three additional indices were generated for Japan, Chinese Taipei and Korea during the meeting in which the standardization included a binomial factor based on the OMZ in the Atlantic (i.e., inside versus outside the OMZ).

This review provided enough information to support the goal of assessing blue marlin during a meeting in 2011.
Document SCRS/2010/012 contains the detailed report of the meeting. No discussion points were raised during the plenary.

### 9.4 Inter-sessional Meeting of the Sub-Committee on Ecosystems

The report of the inter-sessional meeting held in Madrid between May 31 and June 4 was revised by the Group. Main Agenda items (items 2 to 6) included the revision of the new information available on ecosystems, the optimum observer coverage for reliable estimates of by-catch, ecosystem indicators useful for the SCRS, review of the work conducted under the short term by-catch contract and additional information on seabird data collection, assessment and management.

New information was presented about ecosystem models (including SEAPODYM and spatial multispecies production models), and the Ecosystem Considerations section of the IATTC Fisheries Status Report was reviewed, together with new information about by-catch characterization and by-catch mitigation measures. Regarding the optimum observer coverage, the discussion following the documents and analyses conducted during the meeting concluded that optimum coverage depends on both the frequency at which each species is caught and the variability in the amount (i.e. CPUE) of the by-catch, and thus it is difficult to provide a unique observer coverage level for all taxa and all fleets. However, the Group agreed that at minimum observer coverage should be $5-10 \%$. Different ecosystem indicators covering some of the major types of indicators identified in the literature were presented and discussed by the group in terms of data needs, meaning and usefulness. The data available in the ICCAT database was reviewed. The Sub-Committee indicated that these data should be used with caution since reporting of by-catch had been variable in the past. The Sub-Committee also revised the work conducted under the by-catch contract and made several suggestions for improvement. The final report is available as SCRS/2010/047rev. Finally, new information about seabird data collection, assessment and management was presented, including latest advice on mitigation measures that was consistent with the advice provided in 2009.

The Sub-Committee also made a series of Recommendations about by-catch data collection through observer programs, development of reporting mechanisms, and research on by-catch characterization, mitigation measures, ecosystem models and indicators. The Sub-Committee also reaffirmed the recommendations made in 2009 regarding the seabird by-catch mitigation.

Document SCRS/2010/013 contains the detailed report of the meeting.

### 9.5 Mediterranean Swordfish Stock Assessment

The meeting was held in Madrid, Spain, June 28 to July 2, 2010. The Mediterranean Swordfish Executive Summary reflects the major results of this assessment. The detailed report of the meeting can be found in document SCRS/2010/015.

### 9.6 Mediterranean Albacore Data Preparatory Meeting

The meeting (Madrid, June 28 -July 2, 2010) was held at the request of the albacore Species Group during the SCRS to review and prepare in advance of the future reassessment of the stock.

Albacore fisheries are characterised by high spatio-temporal variability in landings and fishing patterns. The gears used are surface longlines, troll and gillnets, mainly in the western Mediterranean. Likewise, baitboats and rod and reel are also used. In the last decade, $69 \%$ of the total Mediterranean catch was reported by Italy, while Greece reported about 20\%, followed by Spain (5\%), Cyprus (4\%) and Turkey (2\%).

Several sport associations in the Mediterranean conducted a survey of its membership regarding the change in availability of albacore in the sport fishery. They indicated that albacore has largely disappeared from these grounds.

Task I nominal catch, Task II catch and effort and size frequencies, as well conventional tagging information, was examined. Of note is the weight of unclassified gear in the overall catches (nearly $100 \%$ in the 1980 s , about $40 \%$ in the 1990s and $30 \%$ in 2000). The discrimination of gears (longline, gillnets) is crucial for fisheries-based characterization and subsequent modelling approaches (catchability of the various fleet components, biomass abundance indices estimations, exploitation rates and selectivity patterns).

The catch and effort data available (SCRS/2010/016, Table 2) evidences the poor coverage of the available statistics when considering the two. At the same time, there is large heterogeneity in the level of stratification (in particular time strata, geographical strata, various efforts units for the same gear) even within the same CPC. This revision should facilitate the CPUE standardization in the future. It was difficult to match the reported data in Task I and Task II, catch and effort data at the fishery level fleet/gear combinations.

The size composition information presents poor coverage (Task II). There are no catch rates estimations from the diverse fleets targeting albacore.

Biological information such as length-weight relationship and growth parameters are partially available from some regions within the Mediterranean. The stock can be classified as data poor. A variety of indicators have been proposed. Evaluation of the robustness of any indicators used for management is essential. Credibility with stakeholders is important, especially where results are based on incomplete data.

The detailed report of the meeting is presented as document SCRS/2010/016.

### 9.7 Bigeye Tuna Stock Assessment Session

Please see item 9.2 that describes the report from the data preparatory meeting (Madrid, Spain, July 5 to 9 , 2010) and the assessment meeting and corresponding discussions. Document SCRS/2010/017 contains the detailed report of the meeting.

### 9.8 Bluefin Tuna Data Preparatory Meeting

The SCRS conducted a data preparatory meeting for Atlantic and Mediterranean bluefin tuna during June 14 to 19, 2010 in Madrid, Spain. The detailed report of the meeting is presented as document SCRS/2010/014.

### 9.9 Bluefin Tuna Stock Assessment Session

The SCRS conducted a comprehensive assessment of Atlantic and Mediterranean bluefin tuna during September 6 to 14 , using the available data (catch, effort and size statistics).

The detailed report of the bluefin tuna assessment meeting was adopted by correspondence during the SCRS plenary (SCRS/2010/018).

## 10. Report of Special Research Programs

### 10.1 Atlantic-wide Bluefin Tuna Research Programme (GBYP)

Dr. Antonio Di Natale, General Coordinator, presented the report on the Atlantic-wide Bluefin Tuna Research Programme (GBYP) activities carried out in 2010.

The report was adopted and is attached as Appendix 6.

### 10.2 Enhanced Research Program for Billfish

The report of the Program for Enhanced Research on Billfish, together with the proposed budget for 2011, was presented by the Program Coordinator, Dr. David Die.

The report was adopted and is attached as Appendix 7.

## 11. Report of the Sub-Committee on Statistics

Dr. Mauricio Ortiz presented the report (Appendix 8) of the Sub-Committee of Statistics which held its session in Madrid, September 27 and 28, 2010. In reviewing the 2009 recommendations from this Sub-Committee, the following were noted: (i) The 2009 Data Confidentiality proposal for ICCAT was still pending approval by the Commission. The Sub-Committee reiterated the importance of this proposal and suggested re-submitting it as the main recommendation from the SCRS this year. (ii) The Secretariat upgraded the internet WiFi hardware for meeting which greatly facilitated network accessibility during 2009/2010 inter-sessional and SCRS meetings.

The main topics of discussion during 2010 Sub-Committee of Statistics meeting were: (i) confusion in the datelines of data submission for the inter-sessional meetings, particularly between data preparatory and assessment meetings; (ii) undefined geographic areas reported for Task I information, and (iii) the report of bycatch information by CPCs.

Finally, the Committee approved the recommendations adopted by the Sub-Committee on Statistics which will be attached to the general recommendations of the SCRS.

## 12. Report of the Sub-Committee on Ecosystems

Dr. Hariz Arrizabalaga, the Convener of the Sub-Committee on Ecosystems chaired the meeting Sub-Committee on Ecosystems presented the report of the meeting held in Madrid, May 17 to 21, 2010 (Appendix 9).

The Committee agreed on the need of completing the databases created by the short-term contracted By-catch Coordinator and keep them operational to be useful and to help achieve the objectives and mandate of the SCRS. In addition, it was recognized the need to work on the by-catch issues agreed by the Joint tuna RFMO Working Group on by-catch in Brisbane. Taking into account the enhanced magnitude of by-catch related work that is anticipated, the Committee supported the request that the Commission funds a full-time By-catch Coordinator position at the Secretariat.

The Committee approved the recommendations adopted by the Sub-Committee on Ecosystems which will be attached to the general recommendations of the SCRS.

## 13. Consideration of implications of the Tuna RFMOs Workshops held in 2010 in Barcelona and Brisbane

### 13.1 Joint Tuna RFMOs Meeting of Experts to Share Best Practices on the Provision of Scientific Advice

Dr. Laurie Kell presented the report of the Joint Tuna RFMOs Meeting of Experts to Share Best Practices on the Provision of Scientific Advice held in Barcelona, Spain, May 31 to June 2, 2010.

Similar problems are faced by all the tuna RFMOs, in that same tuna species are fished worldwide within similar offshore pelagic ecosystems, whilst most tuna fleets and gears are highly mobile using the same technology and selling within similar markets. Therefore, the scientific problems faced in stock assessment by all tuna RFOs are very similar. The workshop reviewed and made recommendations with regard to future priorities in data collection and tuna research in order to allow the RFMOs to provide more efficient and fully transparent scientific advice on their tuna stocks and their pelagic ecosystems.

The Agenda covered (i) routine annual data collection, (ii) biological data (iii) stock assessment, (iv) communication between RFMOs and the world, and (v) enhanced co-operation between tuna RFMOs. In addition, a variety of presentations were made on FAO tuna related activities, the CLIOTOP integrated and coordinated ecosystem-based research for improved scientific advice on tuna fisheries at a global scale, the development of a management procedure by CCSBT, and capacity building by the RFMOs. The report of the meeting and all the presentations are available at http://www.iccat.int/Documents/Meetings/Announce/2010-RFMO/2010-RFMO-1.htm

The main recommendations that came out of the meeting were:

## Routine data collected by year: Catch, effort and size data

1. All members of t-RFMOs are called upon to give a top priority to the provision of data of good quality in a timely manner, according to the existing mandatory data requirements of tuna RFMOs, in order to facilitate the work of tuna RFMOs scientific bodies in the provision of scientific advice based on the most recent information.
2. Lags in the submission of fishery data should be reduced making a full use of communication technologies (e.g. web based) and efforts should be undertaken that basic data formats are harmonized.
3. Efforts should be undertaken so that basic data used in stock assessment (catch, effort and sizes by flag and time/area strata) provided by members should be made available via the websites of tuna RFMOs or by other means.
4. Fine scale operational data should be made available in a timely manner to support stock assessment work, and confidentiality concerns should be addressed through RFMOs rules and procedures for access protection and security of data.
5. Tuna RFMOs should ensure adequate sampling for catch, effort and size composition across all fleets and especially distant water longliners for which this information is becoming limited.
6. Tuna RFMOs should cooperate to improve the quality of data, in particular for methods to estimate: (1) species and size composition of tunas caught by purse seiners and by artisanal fisheries and (2) catch and size of farmed tunas.
7. Tuna RFMOs should use alternative sources of data, notably observer and cannery data, to both validate the information routinely reported by Parties and estimate catches from non-reporting fleets.

## Biological data

8. Regular large scale tagging programs should be developed, along with appropriate reporting systems, to estimate natural mortality growth and movement patterns by sex, and other fundamental parameters for stock assessments.
9. Archival tagging should be an ongoing activity of tagging programs as it provides additional insights into tuna behavior and vulnerability.
10. Spatial aspects of assessment should be encouraged within all tuna RFMOs in order to substantiate spatial management measures.
11. The use of high-resolution spatial ecosystem modeling frameworks should be encouraged in all tuna RFMOs since they offer the opportunity to better integrate biological features of tuna stocks and their environment.

## Stock assessment

12. Tuna RFMOs should promote peer reviews of their stock assessment works.
13. Tuna RFMOs should use more than one stock assessment model and avoid the use of assumption-rich models in data-poor situations.
14. Chairs of Scientific Committees should jointly develop checklists and minimum standards for stock assessments.

## Communication by tuna RFMOs

15. Standardized executive summaries should be developed for consideration by all tuna RFMOs to summarize stock status and management recommendations. These summaries should be discussed and proposed by the chairs of the Scientific Committees at Kobe 3.
16. The application of the Kobe 2 strategy matrix should be expanded and applied primarily to stocks for which sufficient information is available.
17. Tuna RFMOs should develop mechanisms to deliver timely and adequate information on their scientific outcomes to the public.
18. All documents, data and assumptions related to past assessments undertaken by tuna RFMOs should be made available in order to allow evaluation by any interested stakeholder.

## Enhanced cooperation between tuna RFMOs

19. Chairs of Scientific Committees should establish an annotated list of common issues that could be addressed jointly by tuna RFMOs and prioritize them for discussion at the Kobe 3 meeting.
20. Tuna RFMOs should actively cooperate with programs integrating ecosystem and socio-economic approaches such as CLIOTOP to support the conservation of multi-species resources.

## Capacity-building

21. Where determined by a Tuna RFMO, a review of the effectiveness of capacity-building assistance already provided should be undertaken. Reviews of tuna scientific management capacity in developing countries, within the framework of the respective RFMO may also be conducted at their request.
22. Developed countries should strengthen in a sustained manner their financial and technical support for capacity-building in developing countries, notably small island developing States, on the basis of adequate institutional arrangements in those countries and making full use of local, sub-regional and regional synergies.
23. Tuna RFMOs should have assistance funds that cover various forms of capacity-building (e.g. training of technicians and scientists, scholarships and fellowships, attendance to meetings, institutional building, development of fisheries).
24. Tuna RFMOs, if necessary, should ensure regular training of technicians for collecting and processing of data for developing states, notably those where tuna is landed.
25. The structural weaknesses in the receiving mechanism for capacity building within a country should be improved by working closely with Tuna RFMOs

### 13.2 Joint Tuna RFMOs Meeting of Experts on Tuna RFMO Management Issues Relating to by-catch

Dr. Haritz Arrizabalaga presented the report of the International Workshop on tuna RFMO management issues relating to by-catch that took place in Brisbane, Australia, June 23-25 2010, with special emphasis on items related with the SCRS.

The SCRS reviewed the report of the International Workshop on tuna RFMO management issues relating to bycatch that took place in Brisbane, Australia, June 23-25 2010, with special emphasis on items related with the SCRS.

The objectives of the meeting were to review the available information on by-catch, to provide advice to tuna RFMOs on best practices, methods and techniques to assess and reduce the incidental mortality, to develop and coordinate relevant research and observer programs, and to recommend mechanisms to streamline the work of t RFMOs in this field and avoid duplication.

Five background documents were prepared and distributed to the participants summarizing the relevant information available for each of the taxa (turtles, seabirds, mammals, sharks and finfish).

The discussion highlighted the difficulties faced by t-RFMOs to characterize the impact of their fisheries e.g. because impacts from other fisheries not under the mandate of the RFMO need to be considered, as well as some other sources of mortality such as land threats, lack of expertise/knowledge about the by-caught species, lack of data, etc. The group also highlighted the importance of implementing observer programs (with a minimum of $5 \%$ ), and to conduct Ecological Risk Assessments as a way to identify those species which require immediate attention.

The main recommendations with implications for the SCRS are summarized below:

- Adopt standards for by-catch data collection that allow assessing the impact of fisheries on the populations as well as the effectiveness of by-catch measures.
- Evaluate the effectiveness of mitigation measures, as well as the impact on target species. Identify research priorities and facilitate a full compendium of information regarding mitigation techniques.
- As a matter of priority, establish a joint T-RFMO technical working group to promote cooperation and coordination on by-catch issues. The Working Group would include 2-3 representatives from each tuna RFMO, with the following ToRs:
- harmonize data collection protocols
- identify species of concern that require immediate action
- review methods to determine population status
- review analyses to identify factors contributing to by-catch
- review existing mitigation measures and consider the utility of new ones, based on research findings.
- review and compile information on by-catch research and delineate future research priorities.
- Collaborate with the fishing industry, IGOs, NGOs, Universities and other parties as necessary.
- Promote capacity building programs for developing countries

## 14. Consideration of plans for future activities

### 14.1 Annual Work Plans

The rapporteurs presented the 2011 Work Plans for the various Species Groups. These Plans were adopted and are attached as Appendix 5.

Depending on the decision of the Commission, the inter-sessional meetings next year will be Workshop on the use of R, Working Group on the analysis of the BFT aerial surveys, conventional tagging and biological sampling, Working Group on issues related with the SCRS organization, Methods Working Group, blue marlin assessment and white marlin data preparatory meeting, Sub-Committee on Ecosystems, tropical Working Group on the revision of Ghanaian statistics (Phase I), bluefin Working Group on methodological issues and electronic tagging, sharks data preparatory meeting to conduct ecological risk analyses, albacore South Atlantic and Mediterranean albacore assessments meeting; The meeting timetable is attached as Table 14.1.

### 14.2 Inter-sessional meetings proposed for 2011

Taking into account the assessments mandated by the Commission and the Committee's recommendations for research coordination the proposed inter-sessional meetings for 2011 are shown as in Table 14.1. The Committee noted that the schedule is ambitious and that there is a need to maintain some flexibility in order to account for any changes that may result from the deliberations held by the Commission in November 2010 and meetings scheduled by other RFMOs.

### 14.3 Date and place of the next meeting of the SCRS

The next meeting of the SCRS will be held in Madrid from the October 3 to 7, 2011; the Species Groups will meet from the September 26 to 30, 2011.

Table 14.1. Proposed calendar of ICCAT scientific meetings in 2011.

## 15. General recommendations to the Commission

### 15.1 General recommendations to the Commission that have financial implications

## Albacore

The Committee has recommended initiating and focusing on an albacore research program for North Atlantic albacore. Research on North Atlantic albacore depends on available funds supported annually by Contracting Parties individually involved in the albacore fisheries. The research plan will be focussed on three main research areas: biology and ecology, fisheries data, and management advice during a four-year period. Detailed research aims are presented in document SCRS/2010/155. The requested funds to develop this research plan have been estimated at a cost of 4.3 million Euros. Details of the economic plan are provided in the Albacore 2011 Work Plan (Appendix 5).

## Bluefin tuna

The SCRS recommends that a defined methodology should be adopted by the Commission, in order to ensure the regular funding of the Atlantic-wide Research Programme for Bluefin Tuna (GBYP) to support the regular follow-up of the programme and provide all CPCs concerned a method to calculate their voluntary contribution.

The SCRS recommends that all CPCs concerned shall provide the necessary support to the Atlantic-wide Research Programme for Bluefin Tuna (ICCAT-GBYP) in order to:

- help the ICCAT Secretariat initiatives in the framework of the GBYP, particularly for contacts with the national Authorities concerned;
- ensure assistance for the necessary permits concerning the GBYP activities in their territorial waters or airspace;
- provide the necessary contacts at the national level for ensuring the regular development of the GBYP.

The Commission should consider the merits of a research TAC set aside to help fund the GBYP. A research allocation of up to 50 t could be quite beneficial in supporting the GBYP research enterprise while reducing the necessity for voluntary contributions for the program.

Fishery-independent information is crucial to reduce uncertainty in assessment models that would otherwise be based only on catch and fishing effort data, particularly when those data become biased owing to management regulations. The Committee strongly recommends the development of a large-scale tagging program and fisheryindependent surveys of abundance to better track trends in biomass and better estimate fishing mortality rates.

Given the above two concerns, it is essential that the Commission seek the means to fully fund the GBYP.

## Billfish

The Commission should increase the contribution to the Enhanced Billfish Research Plan by 10,000 Euros in 2011 to allow the plan to be fully accomplished.

## Tropical tunas

The Committee recommends the implementation of a broad-scale "Atlantic Ocean Tropical Tuna Tagging Program (AOTTP)", starting in 2011, for a duration of five years and a total cost close to $11,400,000$ Euros (see Appendix 5)

## Sub-Committee on Ecosystems

The SCRS recommends implementing observer and logbook programs, as soon as possible, to permit quantifying the total catch (including by-catch), its composition and disposition. The initial minimum observer coverage recommended is $5-10 \%$, although the precision of by-catch estimates might remain low for certain species and higher coverage may be warranted depending upon the Commission's objectives.

Moreover, the magnitude of by-catch related work is continuously increasing and it is essential that the Commission fund a full-time By-catch Coordinator position at the Secretariat to make all the information operational and useful for the mandate of the SCRS.

Work on harmonization of by-catch related activities with other Tuna RFMOs.

## Sub-Committee on Statistics

Due to the overall and increasing workload, the Committee is concerned that the structural support available to the Secretariat, may not be sufficient enough to respond to these tasks and responsibilities regarding scientific and compliance related tasks, particularly the use of more complex models which are going to require much more support as concerns the preparation of data. Consequently, the Committee recommends that an evaluation be carried out on the structural work and human needs aimed at considering foreseeable difficulties.

### 15.2 Other recommendations

## Albacore

In order to carry out the assessment of the South Atlantic stock [Rec. 07-03] in 2011, it is recommended that scientists involved with surface (Namibia and South Africa) and longline (Chinese Taipei and Japan) fleets participate in the assessment session. Otherwise the results from the analyses might suffer from the lack of expertise on the nature of the data and the information available.

In the case of the first attempt to assess the Mediterranean albacore stock it is emphasized to follow the Work Plan and recommendations from the Data Preparatory meeting (SCRS(2010/015), as well participation from scientists with expertise on the main fisheries exploiting the stock.

## Bluefin tuna

The Committee reiterated that it is essential to obtain representative samples of otoliths and other tissues from all major fisheries in all areas. Such collections will provide direct estimates of the age composition of the catch (avoiding the biases associated with determining age from size), direct estimates of the stock of origin (a key factor to improve our ability to conduct mixing analyses) and will help in verifying current assumptions concerning age-at-maturity and fecundity-at-age. This activity should be coordinated with the GBYP.

## Tropical tunas

The Committee is supportive of research programs to mitigate by-catch in purse seine fisheries (especially on FADs), such as the program that ISSF has initiated. The Committee notes that some issues and potential solutions are region-specific, and therefore recommends that part of the research be conducted in the Atlantic Ocean.

The Committee noted that some national scientists would like to access the cannery data that ISSF-participating companies are submitting to the Secretariat. This would be extremely useful in several ways. For example, in cases where those national scientists have vessel logbooks which could be matched with the cannery information on a trip-by-trip basis, thus allowing for improved estimates of catches by species. For this reason, the Committee encourages the development of MOUs that will allow these national scientists to access the data while protecting the confidential components of the ISSF data submissions.

## Small tunas

Include blackfin tuna (Thunnus atlanticus) in the small tunas chapter of the ICCAT Manual and include dolphinfish (Coriphaena spp.) among the species considered by the ICCAT Small Tunas Species Group.

## Sharks

Due to the vulnerability and deficient statistical information on these species, it is essential to advance in research and the collection of data in order to assess the stocks.

The Committee recommends that the countries generate research programs to minimize by-catch and the discard mortality of sharks.

The Committee recommends continuing activities with the ICES Working Group on Sharks, participating in the porbeagle data preparatory meeting that ICES will hold in 2011, and in the future assessment to be carried out in 2012.

Considering that Carcharhinus longimanus is found among the five species with the highest risk in a Ecological Risk Assessment carried 2008, that it makes up a small part of the catches, has high rates of survival and is easily identifiable, that a significant proportion of its catches is comprised of juveniles, the Committee recommends that research be conducted to better determine which life stages are important for the productivity of the stock.

## Swordfish

Working Group participation. The SCRS noted that attendance at inter-sessional meetings is becoming an increasing concern. For example, during the recent Atlantic swordfish assessment, one of the longest CPUE time series was submitted by correspondence, without the author or another scientist familiar with the analyses being present at the meeting. This made it difficult to evaluate the suitability of the time series. The Committee recommends that CPCs that can make valuable contributions to the assessments make the necessary arrangements to ensure the presence of their national scientists at those meetings.

## Sub-Committee on Ecosystems

The SCRS recommends that research be conducted on measures to mitigate by-catch in ICCAT fisheries. The research should include the effect of mitigation measures on both by-catch and target species. The SCRS further recommends that CPCs periodically submit summary reports to the SCRS on subjects like by-catch characterization, trends in by-catch rates, effect of mitigation measures, etc.

## Assessments and methods

Regarding standardizing practices among tuna RFMOs, the Committee concluded that harmonization should be encouraged between RFMOs for data inputs, data structure and data formats, but not necessarily for assessment methods. The Committee encourages making data available on the web, that can be used in meta-analysis type research for highly migratory species. To facilitate this harmonization process, the Committee recommends holding joint meetings with scientists from other tuna RFMOs.

## Sub-Committee on Statistics

The Committee reiterates the importance of adopting the Data Confidentiality Policy for the ICCAT Secretariat, and reminds the Commission that a proposal was approved and presented by the SCRS in 2009. The Committee also resolved that the Data Confidentiality Policy will be resubmitted to the Commission at the 2010 ICCAT Commission Meeting.

The Committee approved the protocol prepared by the Secretariat regarding travel funding for scientific meeting participation and recommended that at a minimum, two-week lead times be obligatory for requesting travel funds.

## 16. Responses to Commission's requests

### 16.1 Defining a standardized methodology for the collection of sport and recreational fisheries data for all species under the ICCAT mandate, including estimates of post-release mortality and data from sampling, tagging and counting programs

In 2006, the Commission resolved that the SCRS should establish a Working Group to evaluate sport and recreational fishing activities. The Working Group would:
a) Examine the biological and economic impact of recreational and sport fishing activities on ICCAT managed stocks and assess the level of harvest.
b) Based on available information, identify approaches for managing the recreational and sport fishing activities in ICCAT fisheries.
c) Report the results of deliberations to the Commission and, as appropriate, propose recommendations for next steps to manage the recreational and sport fishing activities in the Convention area. CPCs shall report prior to the Working Group meeting the techniques used to manage their sport and recreational fisheries and methods used to collect such data.

With regard to item (a), the group recognized that recreational and sport fishing activities can have considerable biological and economic impact on ICCAT managed stocks. Furthermore, these impacts are not currently estimable due to a general lack of data.

With regard to item (b), the group recognized that the evaluation of suitable management measures requires reliable statistics be reported by all CPCs with non-trivial recreational and sport fisheries, and would be further improved by concomitant socio-economic data. The group recommended enhanced efforts by CPCs to collect and report such information.

With regard to item (c), the CPCs that attended the group made reports on their sport and recreational fishing activities, and the techniques used to collect data and manage these activities. These reports have been compiled, and will be reported to the SCRS during the 2011 Meeting of the Working Group on Stock Assessment Methods.

TAKING INTO ACCOUNT the need to improve stock assessments by obtaining reliable estimates of total removals (harvest + dead discards) of ICCAT managed stocks; the Committee recommended the following:

1) In order to develop appropriate estimates of harvest and dead discards by recreational and sport fishing activities, the SCRS recommended that each CPC:
a) Identify the "universe" of recreational fishing participants.
b) Sample that universe with appropriate coverage to allow estimation of total removals with sufficient accuracy and precision.
c) Produce or obtain estimates of release mortality to facilitate the quantification of fish released alive that subsequently die due to interaction with fishery.
2) The Committee concluded that sufficiently accurate and precise estimates of total recreational removals require CPCs to collect the following information through national and/or regional sampling programs. This data would be retained by CPCs, but used to develop the estimates of total recreational removals that are reported to ICCAT. The following should be considered minimum standard practices. These are the essential components for estimation of Task I and Task II data to meet reporting obligations.
a) Catch by species
b) Length/Weight of landed fish
c) Discards by species
d) Length/Weight of discarded fish
e) Disposition of discards (e.g. released alive and likely to survive, released alive but unlikely to survive, discarded dead, used for bait).
f) Location and time of fishing trip
g) Estimates of release mortality by species
3) The Committee acknowledged that some CPCs have already developed successful sampling programs, and currently use data collected by these programs to report recreational Task I and Task II statistics to ICCAT. Several of these programs were identified by the group, and the methodologies were discussed. This information will be re-compiled, and will be further evaluated by the SCRS in 2011.

### 16.2 Continuation of the evaluation of data elements pursuant to Rec.05-09

In response to the Commission Res. [05-09], the SCRS through the Sub-Committee on Statistics and the Secretariat prepare each year a summary of the impact on stock assessment and evaluations from the lack of, deficiencies and limitations of data available for the Working Groups. Since 2007, a questionnaire has been distributed to the rapporteurs of each working group that had an assessment or data preparatory meeting during the year. The questionnaire attempts to collect the working group data availability and impact on their analysis, as well specific recommendations to improve their assessment work. During 2010, three ICCAT species were
assessed: bluefin tuna east and west stock units, the bigeye tuna stock and the Mediterranean swordfish stock. Besides, two data preparatory meetings were held, for the Mediterranean albacore stock and for the blue marlin stock. Document SCRS/2010/165 includes the response to the questionnaires by the Chairs of the respective Working Group in 2010.

### 16.3 Identify as precisely as possible BFT spawning grounds in the Mediterranean in view of the creation of sanctuaries [Rec. 08-05]

The 2008 Recommendation Amending the Recommendation by ICCAT to Establish a Multi-annual Recovery Plan for Bluefin Tuna in the Eastern Atlantic and Mediterranean [Rec. 08-05], paragraph 25, requests that for the annual meeting of the Commission in 2010 the SCRS identify as precisely as possible spawning grounds in the Mediterranean in view of the creation of sanctuaries.

Information has been gathered over a number of years about the location and timing of bluefin spawning in the Mediterranean. While considerable literature is known to exist with which to characterize spawning areas and oceanographic covariates in the region, a complete synthesis of this information will require considerable time and further investigation in order to compare historical knowledge with more contemporary observations. A complete characterization of bluefin spawning in the Mediterranean will also require a better understanding of the biology of bluefin and its importance in achieving management objectives; an objective of the GBYP.

The most contemporary, although provisional and likely incomplete without fishery independent information view of spawning locations in the Mediterranean, considering overlap with the fishery, comes from the VMS data now required for purse seine (and other) vessels fishing for bluefin in the Mediterranean during the spawning period (mid-May through mid-July). To this end, concentrations of purse seine vessel locations on fishing grounds can give a generalized view of the regions where schooling bluefin are susceptible to capture during spawning and pre-spawning aggregations. The 2008-2009 purse seine VMS data were used to identify spawning locations for which the GBYP aerial surveys of the bluefin spawning stock were conducted in 2010 (Figure 16.3). It is noteworthy that these areas are consistent with scientific knowledge available to SCRS. While spawning is known to have occurred outside of these general areas on the basis of location of larvae and other information, these 6 primary areas are believed to represent the dominant spawning areas in the recent past and also represent areas with heavy concentrations of fishing effort during the past few years. With additional data collected through the GBYP, a more refined and comprehensive evaluation of spawning areas and behaviors of bluefin in the Mediterranean will be possible.

Figure 16.3. Spawning areas identified through analysis of VMS data used in the 2010 GBYP aerial survey program for surveying spawning biomass in the Mediterranean.

### 16.4 Review of information on farmed bluefin tuna growth rates [Rec. 06-07; 08-05]

The 2008 Recommendation by ICCAT Amending the Recommendation by ICCAT to Establish a Multi-Annual Recovery Plan for Bluefin Tuna in the Eastern Atlantic and Mediterranean [Rec. 08-05] states:
> 96. "Each CPC shall define growth factors to be applied to bluefin tuna farmed in its cages. It shall notify to ICCAT Secretariat and to the SCRS the factors and methodology used. The SCRS shall review this information at its annual meetings in 2009 and 2010 and shall report to the Commission. The SCRS shall further study the estimated growth factors and provide advice to the Commission for its annual meeting in 2010."

At the 2009 SCRS meeting, the Committee reviewed several industry-sponsored studies and concluded that the gain in weight of bluefin tuna in farms can be significantly higher than the value which has been used to-date (see SCRS/2009/192). The Committee recommended that Contracting Parties tentatively adopt growth factors that are consistent with those in Table 16.6 of the 2009 SCRS Report, although the Committee advised it is important to note that these growth factors do not take into account any of the losses that are known to occur (e.g., due to mortality, escapees and other sources of loss). The Committee advised that applying these factors to an amount of harvested bluefin in order to estimate the initial caged amount will likely result of an underestimate of the input to the cages.

In 2010, the Committee examined the implications of these growth factors by their application to observations from the Japanese fresh auction market weight distributions and found application of the weight gain rates from Table 16.6 ( 2009 SCRS Report), resulted in back-calculate fish weights at initial capture which seemed to show unrealistic size distributions, in that more fish below the 30 kg minimum are calculated as having been caught than would be expected given existing controls. The Committee reemphasized concern about using the available farmed bluefin tuna growth rates (SCRS/2009/192, 2009 SCRS Annual Report) to back-calculate individual fish weight, since those rates seem to represent a maximum weight gain that might be obtained only under the best of conditions; the consequence of the overestimation of growth rates would be an underestimate of sizes at original capture, such as appears to be occurring in application of these rates to recent observations.

The Committee also recommends that Contracting Parties continue to conduct studies that can lead to a better quantification of the inputs into cages. This includes average growth factors that take losses into account. However, more importantly, it is necessary to develop methods to measure the size of the fish entering the cages.

As real size samples at time of the catch are needed to significantly decrease uncertainties in future stock assessment, it is necessary to routinely use a system (dual camera system or any other operational technology) that will provide sizes of fish entering into cages. Therefore, the SCRS strongly encourages the farms to test these systems that have been recently developed as soon as possible.

### 16.5 Review of data availability on the interaction of tuna fisheries on seabirds and sea turtles

ICCAT [Res. 03-11] encouraged CPCs to report data of interaction of their fleet with sea turtles in the Convention area. Similarly, [Rec. 07-07] required the submission of similar data for seabirds. Reporting of bycatch information is essential to characterize the degree of interaction of by-catch species with ICCAT fisheries and to assess the overall impact of these fisheries on these species.

In 2009, the SCRS completed a seabird assessment. During the assessment, only a limited number of CPCs provided detailed information about interactions with seabirds, which greatly limited the assessment results (see Response to 07-07 in 2009). Information on by-catch has typically been made available in the form of SCRS documents. But, formal statistical submissions of information related with seabird and sea turtle interactions have not been possible due to the lack of established formal submission mechanisms for by-catch data (e.g. electronic forms, etc.)

During 2010, the By-catch Coordinator compiled into a database the by-catch information available in different working documents, peer reviewed publication and reports. The By-catch Coordinator and the SCRS identified the minimum data requirements to characterize the quantity, species composition, and disposition of the bycatch. These requirements included species identification, quantities (in number or weight), an indication of sizes, fate (kept, released alive or discarded dead), and proportion of fishing effort observed or sampled.

Although some of this information can be submitted using the existing reporting electronic forms, the SCRS requested the Secretariat to develop as soon as possible electronic forms specific for by-catch to facilitate the reporting of this type of information. It is recommended that CPCs submit their by-catch information using these new forms as soon as they become available.

### 16.6 Review of Ghana's action plan to strengthen the collection of statistical data

In 2009, the Commission requested Ghana to submit to ICCAT an action plan in order to strengthen the collection of statistical data (Task I and II, including size composition) and to develop control measures so as to ensure the full implementation of conservation and management measures (paragraph 5, Rec. 09-01). Thus, Ghana presented the document "Ghana's action plan to strengthen the collection of statistical data (Task I and Task II) and control measures to ensure the full implementation of conservation and management measures" (ICCAT Circular \#908/10).

In summary, this plan intends to assure the collection of Task I and Task II fishery statistics by means of (i) obtaining data from the tuna canneries which will allow to breakdown the total catch of Ghanaian vessels by species (Task I); (ii) completing and submitting to Ghanaian authorities the ICCAT logbooks after every fishing trip which will be required by law (for Task II); (iii) increasing the number of sampled fish, following SCRS recommendation, to 500 individuals per vessel and trip (Task II size); and (iv) including observers onboard in every purse seiner. In order to assure that all Ghanaian flag vessels are covered under this action plan, Ghana has signed an MoU with Côte d'Ivoire to sample vessels that unload tuna at the port of Abidjan. Finally, as a control measure, the fishery licenses will be renewed quarterly provided that catch data and logbook data are correctly submitted.

The Committee acknowledges the commitment made by Ghana to strengthen the collection of statistical data and hopes that Ghana will make available the human and financial resources necessary to achieve this plan. The Committee encourages Ghanaian scientists and any other interested parties to continue the analysis and revision of Ghanaian statistics. The Secretariat informed that some data from the Ghanaian fleet unloading tuna in Abidjan were already received, although improvement in the format is required before they can be analysed.

The Committee notes that there may be subtle differences in the sampling programs to collect fishery statistics for purse seiners in Abidjan and it would be convenient that both sampling programs follow the same standard and criteria in order to facilitate joint analysis of standardized data. In that sense, as different teams are responsible for the Ghanaian and European purse seine sampling in Côte d'Ivoire, it would be convenient to enhance collaboration and coordination between both groups. The Committee recommends, as a first step, that a SCRS document explaining in detail how the Ghanaian sampling program is carried out be prepared by Ghanaian scientists.

The Committee also discussed specific issues related to the Ghanaian sampling program as well as to the plan of work in order to review and analyse actual and past Ghana fishery statistics. For example, the issue of whether the "faux-poisson" is computed in the logbooks or not was discussed; which can be cross-checked based on logbook data and observer onboard data. Similarly, it was commented that various projects with the aim to improve Ghanaian fishery statistics have been carried out in ICCAT; which will need to be reviewed to get a general overview of the current situation of Ghanaian Statistics.

In light of those issues, the Committee recommends the establishment of a Working Group with the participation of scientists who are familiar with the fishery in the region in order to analyse and study different approaches to improve the collection of Ghanaian fishery statistics as well as revise past data.

The Terms of Reference of this Working Group are described in the Tropical's Work Plan for 2011.

### 16.7 Evaluation of the effect of the closure contained in [Rec. 08-01] and alternative closures

In 2008, the Commission requested the SCRS to evaluate the closure contained in the proposal from Ghana and Côte d'Ivoire (Annex 1 of Rec. 08-01), and any alternative closure, taking into account the need to reduce the catch of juvenile fish, and make appropriate recommendations to improve the closure.

The Committee considered in its 2009 meeting the past FADs moratoria [Rec. 99-01], the current FADs moratoria, [Rec. 04-01] and the proposed FADs moratoria Annex 1 of [Rec. 08-01]. However, it should be noted that the data available to the Committee are not of sufficient detail and quality required to allow carrying out this
sort of evaluation in a fully satisfactory manner. For example, there was a lack of catch statistics of a major country in this fishery. Moreover, the lack of compliance of past/present moratoria in addition to the changes in the population/fishery, which have occurred in the period studied due to an important effort reduction, make it difficult to separate moratorium and effort reduction effects in the reduction of juvenile catch. Therefore, in general the results presented below should be considered inconclusive in evaluating the effect of the FADs moratoria contained in Annex 1 of Rec. 08-01. Nevertheless, and based on the analysis carried out by the Tropical Tunas Species Group meeting, the Committee provides the advice below.

The Committee had to make a number of assumptions in order to develop a spatially-structured time series of catch and effort data for the major fleets (EU and Ghana). These data show clearly that the major catches on FADs that were observed in the moratorium area before its 1997-2000 implementations have not been observed during recent years.

Moreover, the first [Rec. 99-01] moratorium on FADs substantially reduced the catches of small bigeye for some fleets in the closed area, although this benefit was partially offset by increase catches of small fish, both bigeye and yellowfin, outside the closed area and inside by non-compliant vessels, which makes it difficult to appraise the effectiveness of the past moratorium. The Committee's analyses indicate that, compared to the current closure, the past moratorium reduced the catches made by European and associated fleets on FADs. This conclusion was also supported by a preliminary analysis presented to the Committee examining direct indices of abundance within the moratorium areas.

The Committee also conducted per-recruit analyses to address the potential effects of changes in relative effort among gears including changes in FAD effort. The Committee notes that the results of these analyses rely heavily upon the assumed value of natural mortality for small fish, which is highly uncertain. The results of these analyses confirm previous conclusion that modest gains in YPR for yellowfin and bigeye can be obtained by simultaneously considerably decreasing the FAD fishing mortality and increasing the fishing mortality exerted by the other fleets. The results also show that increases in effective effort levels, particularly that of the FAD fleets, would likely result in substantial reductions in SPR. One implication of these results is that it would be more difficult to maintain spawning stock biomass at high levels under scenarios such as a reallocation of surface fleet effort from other oceans toward the tropical Atlantic. The Committee did not conduct similar analyses for skipjack. However, taking into account the biological characteristics of this species, it was considered that the application of measures such as time-area closure should not produce gains in YPR but should result in foregone skipjack catches that would be proportional to the size of the area closed and the period of closure.

Additional analysis of the European surface fleet performance before and after the various moratoria that have been agreed was undertaken as a way to evaluate the potential effects of the alternative time-area closure defined in [08-01]. Regarding the voluntary moratoria on FADs and the ICCAT recommendations (98-01, 99-01) they appeared to fulfill the objective of reducing sets on FADs and therefore a decrease on their catches, especially the juveniles (Figure 16.7-1). Regarding the ICCAT recommendation 04-01, inside this moratorium the EU purse seine fleet did not make fishing activities inside the closure area once the closure entered into force, fulfilling this objective. However, the moratorium was not large enough, both the length of time and the surface area to noticeably reduce fishing activities.

There was high presence of the fleet during the proposed months to the left side outside the proposed area in [0801]. This could result in an increase of fishing effort with the use of FADs around the area. Extending the proposed area westward might improve the efficacy of this proposed time-area closure (Figure 16.7-2).

An evaluation of the available tagging data from the periods before and during the moratoria was also conducted. The amount of tag and recapture information from these periods was not sufficient to draw any firm conclusions regarding the efficacy of the different moratoria. Additional large-scale tagging experiments would be required to address this question.

As previously noted, the Committee is unable to provide a comprehensive and quantitative evaluation of the proposed moratoria described in Annex 1 of Rec. 08-01 due to the limitations described previously. Work planned for 2011 to reexamine in detail the Ghanaian data may provide an improved basis for this evaluation. However, there is a general agreement that larger time/area FAD moratoria are likely to be more precautionary than a smaller FAD moratoria, providing that reductions in juvenile mortality are necessary to achieve management objectives and observers are present to verify the compliance with any FAD moratorium.

Figure 16.7-2. Area distribution of the total catches made by European purse seiners; Figure 2a: before (20002004) and Figure 2b: during (2005-2009) the implementation of the complete closure for the surface fishery in the so-called Piccolo area in the month of November.

### 16.8 Reporting on the bluefin scientific data coverage level achieved by each Contracting Party observer program [Rec. 08-05]

The 2008 Recommendation Amending the Recommendation by ICCAT to Establish a Multi-annual Recovery Plan for Bluefin Tuna in the Eastern Atlantic and Mediterranean [Rec. 08-05], established two observer programs, one for Contracting Parties to implement, and a Regional one for the Secretariat to manage.

The Recommendation states that the Commission will develop a set of requirements and procedures that, taking into account Contracting Party confidentiality requirements, will allow the data collected under these programs to be provided to the SCRS. Furthermore, for the scientific aspects of the program, the Recommendation asks the SCRS to report on the coverage level achieved by each Contracting Party, to summarize the data collected, and to make recommendations for improvement.

### 16.8.1 Regional Observer Program (ROP-BFT)

- Vessels

Target observer coverage is $100 \%$ on purse seine vessels over 24 m during the entire annual fishing season and on all purse seiners involved in joint fishing operations. In addition, observers shall be present during all transfer of bluefin tuna to and harvest from the cages. The Recommendation entered into force after the 2009 purse seine fishing season, and therefore Contracting Parties were asked to use their own Contracting Party observer programs if they wished to fully implement the provisions of this Recommendation even before it was officially in force.

A call for tenders was issued in September 2009 with a view to awarding the contract before the 2010 fishing season. A consortium was selected and contracted for the implementation of the programme on both vessels and farms.

Observers were recruited and trained for deployment on 94 vessels as follows:

| Flag vessel | Observers |
| :--- | :---: |
| Croatia | 12 |
| EU | 24 |
| Korea | 1 |
| Libya | 17 |
| Morocco | 1 |
| Tunisia | 21 |
| Turkey | 18 |

Two of these vessels (one Libyan and one Turkish) did not fish due to technical problems. At the time of writing, most observers had disembarked from their vessels and are currently undergoing debriefing.

The data obtained from the vessel observer program has, thus far, little, if any, scientific value, since observers are principally concerned with monitoring compliance with the requirements of [08-05]. Recommendations below, if they are implemented in 2011 and beyond could result in significant information in support of stock assessments (see Recommendations).

- Farms

Rec. [08-05] also calls for the ROP to have observers in farms during all caging and harvests. In 2009, the Secretariat implemented the programme for harvests for two Contracting Parties. In 2009, some CPCs participated in the ROP for farms and scientific data were collected and provided to ICCAT. These data, from Croatian and Turkish farms, have not yet been fully incorporated into the assessment databases, since they were delivered to the Secretariat in late September, 2010. In the future, the scientific data collected through these programs should be reported in a more timely manner and adhere to the established reporting deadlines for Task I and Task II reports. In 2010, four Contracting Parties have indicated their intention to participate (Croatia, EU, Tunisia and Turkey). Some harvests have been covered and deployments for caging are currently ongoing. Some raw data are available but to date is incomplete. Size samples have been collected during the harvests. The data are sent to the Contracting Parties concerned and can be included in the Task II submissions as required by Rec. 08-05.

### 16.8.2 Contracting Party Observer Program

The national Observer Program requires the following coverage levels:

[^10]By the 2010 SCRS meeting (Bluefin Tuna Data Preparatory Meeting) only Japan and Morocco had provided the coverage levels ( $20.1 \%$ for Japan and $100 \%$ for Moroccan traps) of its national Observer Programs (SCRS/2010/066, Annual Report of Morocco). For the rest of CPCs some information is available on their target coverage levels, but not about the actual coverage achieved or the data collected

## Recommendations

In order to facilitate the reporting of observer coverage achieved by Contracting Parties, the Committee continues to recommend that the Secretariat develop appropriate reporting forms taking into account the SubCommittee on Ecosystems and the Kobe II By-catch reports for 2010, and that it request CPCs to provide the information. At a minimum, the information that should be recorded by observers includes species identification, quantity, size, and fate, as well as the ratio of observed to exerted fishing effort. It is also recommended to record catch of all species so as to have a complete characterization of total removals.

The SCRS also believes that it may be useful for the Commission to consider the "Suggested Rules and Procedures for the Protection, Access to, and Dissemination of Data Compiled by ICCAT" (Appendix 10 of the 2009 SCRS Report), as these may assist the Commission in its development of requirements and procedures for the submission of observer data.

Furthermore, the Committee continues to recommend that the Commission require scientific work from observers in both the Contracting Party Observer Program and in the ROP (paragraph 88 and Annex 7 of Rec. [08-05] state that "...the observer shall carry out scientific work, such as collecting Task II data, when required by the Commission, based on the instructions from the SCRS"). Such scientific work should cover the following:

- Representative size samples
- Catch and fishing effort information
- Access to biological samples when feasible
- In general, activities in support of the Bluefin Research Program (GBYP)

## 17. Other matters

### 17.1 Continued Involvement with ISSF

The International Seafood Sustainability Foundation (ISSF) is an NGO formed by some of the major tuna canning interests and WWF, which aims to undertake science-based initiatives for the long-term conservation and sustainable use of tuna stocks. ISSF invited Dr. Gerald Scott to become a member of their Scientific Advisory Committee. The role of the Advisory Committee, conformed by scientists who are familiar with the various tuna RFMOs, is to review a scientific report that is written by ISSF ensuring that it is consistent with the scientific assessments produced by the RFMOs. Dr. Scott participated in a meeting of the Scientific Advisory Committee on April 13-16 in La Jolla, USA. In addition, ISSF participating companies have been providing data on catches directly to ICCAT (and other FMOs) and, as indicated in a letter received on October 1, 2010 (Appendix 10), it is the intention of ISSF in providing these data sets for them to be used in a meaningful way by the RFMO scientific bodies. In order for national scientists to conduct the analysis needed to improve the working of the Scientific Committee as part of the ICCAT process, ISSF suggested that a mechanism that allows to access the data in a manner that maintains confidentiality, and within the frameworks that have already been established (i.e., ICCAT working group for tropical tunas, etc.) should be developed to support these research initiatives.

The Committee noted that some national scientists would like to access the cannery data that ISSF-participating companies are submitting to the Secretariat. This would be extremely useful in several ways. For example, in cases where those national scientists have vessel logbooks which could be matched with the cannery information on a trip-by-trip basis, thus allowing for improved estimates of catches by species. Such work will be necessary to complete the 2011 work plan for tropical tunas and for this reason, the Committee encourages development of mechanisms that will allow these national scientists to access the data while protecting the confidential components of the ISSF data submissions. A framework for such a mechanism was discussed and adopted by the 2009 SCRS (see Attachment 2 to Addendum 3 in the 2009 SCRS Report).

## 18. Election of the Chairman

Brazil nominated Dr. Josu Santiago (EU) as Chair of the SCRS; the nomination was seconded by Ghana. Dr. Santiago was elected unanimously. The new SCRS Chair thanked everyone and stated that he had been rapporteur for albacore in the past but had to leave the SCRS when he became involved in management. However, he has been attending the Commission meetings and noted the increase in the work load of the SCRS, although he had not expected to take on the challenge and responsibility of the SCRS chairmanship. He thanked all the Chairs who had preceded him and stated that being Chair of the SCRS will be a challenge and that he would appreciate the support and help of the SCRS and the Secretariat.

The outgoing Chair, Dr. Jerry Scott, thanked everyone for their support during his chairmanship and offered his help to the incoming Chair, if needed. The Executive Secretary noted that it was difficult to say goodbye and expressed his appreciation for the great contribution that Dr. Scott had made during his chairmanship. Dr. Scott had chaired the SCRS well and, in particular, had been very successful in conveying results to others. He was key in the development of the Kobe matrix, which should really be called the "Scott matrix". The Executive Secretary wished Dr. Scott good luck and hoped to still see him at meetings of the SCRS. Finally the Executive Secretary welcomed Dr. Santiago and stated that he will have the support of the Secretariat. He then presented Dr. Scott with an engraving of a bluefin tuna trap.

Finally, Dr. Alain Fonteneau (EU) praised the quality of the work done by the ICCAT Secretariat, particularly the website and the Statistical Bulletin. He remarked on the incredible efficiency of the Secretariat compared with elsewhere. Dr. Jerry Scott also praised the work of the Secretariat, not just those who work first hand with the SCRS, but also those who actively work behind the scenes, including the interpreters.

## 19. Adoption of Report and closure

The SCRS Chairman expressed his gratitude to the participants for their collaboration and congratulated the Secretariat for the excellent work carried out.

After congratulating the Committee for its work, the Executive Secretary acknowledged the professionalism and efficiency of the Secretariat staff and the interpreters who work for ICCAT.

The Report of the 2010 SCRS meeting was adopted.
The 2010 Meeting of the SCRS was adjourned.

## AGENDA OF THE

 STANDING COMMITTEE ON RESEARCH AND STATISTICS (SCRS)1. Opening of the meeting
2. Adoption of Agenda and arrangements for the meeting
3. Introduction of Contracting Party delegations
4. Introduction and admission of observers
5. Admission of scientific documents
6. Report of Secretariat activities in research and statistics
7. Review of national fisheries and research programs
8. Executive Summaries on species including the Kobe matrix with the corresponding levels of catch for bluefin and bigeye tunas [Res. 09-12]:

YFT-Yellowfin, BET-Bigeye, SKJ-Skipjack, ALB-Albacore, BFT-Bluefin, BIL-Billfishes, SWO-Atl. Swordfish, SWO-Med. Swordfish, SBF-Southern Bluefin, SMT-Small Tunas, SHK-Sharks
9. Report of inter-sessional meetings
9.1 Working Group on Stock assessment methods
9.2 Bigeye Data preparatory meeting
9.3 Blue Marlin Data Preparatory meeting
9.4 Inter-Sessional Meeting of the Sub-Committee on Ecosystems
9.5 Mediterranean swordfish Stock Assessment
9.6 Mediterranean albacore Data Preparatory meeting
9.7 Bigeye Stock Assessment session
9.8 Bluefin Data Preparatory meeting
9.9 Bluefin Stock Assessment session
10. Report of Special Research Programs
10.1 Atlantic Wide Research Programme for Bluefin tuna (GBYP)
10.2 Enhanced Research Program for Billfish
11. Report of the Sub-Committee on Statistics
12. Report of the Sub-Committee on Ecosystems

13 A Consideration of Implications of the Tuna RFMOs workshops held in 2010 in Barcelona and Brisbane.
14. Consideration of plans for future activities
14.1 Annual Work Plans
14.2 Inter-sessional meetings proposed for 2011
14.3 Date and place of the next meeting of the SCRS
15. General recommendations to the Commission
15.1 General recommendations to the Commission that have financial implications
15.2 Other recommendations
16. Responses to Commission's requests
16.1 Defining a standardized methodology for the collection of sport and recreational fisheries data for all species under the ICCAT mandate, including estimates of post-release mortality and data from sampling, tagging and counting programs.
16.2 Continuation of the evaluation of data elements pursuant to Rec. 05-09.
16.3 Identify as precisely as possible bluefin tuna spawning grounds in the Mediterranean in view of the creation of sanctuaries Rec. 08-05.
16.4 Review of information on farmed bluefin tuna growth rates Rec. 06-07 and 08-05.
16.5 Review of data availability on the interaction of tuna fisheries on seabirds and sea turtles.
16.6 Review of Ghana's action plan to strengthen the collection of statistical data.
16.7 Evaluation of the effect of the closure contained in [Rec. 08-01] and alternative closures.
16.8 Reporting on the bluefin scientific data coverage level achieved by each Contracting Party observer program [Rec. 08-05].
17. Other matters
18. Election of the Chairman
19. Adoption of report and closure

## LIST OF 2010 SCRS DOCUMENTS

| Number | Title | Author(s) |
| :---: | :---: | :---: |
| SCRS/2010/010 | Report of the 2010 ICCAT Working Group on Stock Assessment Methods (Madrid, Spain, April 21 to 23, 2010). | Anonymous |
| SCRS/2010/011 | Report of the 2010 ICCAT Bigeye Tuna Data Preparatory Meeting (Madrid, Spain - April 26 to 30, 2010). | Anonymous |
| SCRS/2010/012 | Report of the 2010 ICCAT Blue Marlin Data Preparatory Meeting (Madrid, Spain - May 17 to 21, 2010). | Anonymous |
| SCRS/2010/013 | Report of the 2010 Inter-sessional Meeting of the SCRS Sub-Committee on Ecosystems (Madrid, Spain - May 31 to June 4, 2010). | Anonymous |
| SCRS/2010/014 | Report of the 2010 ICCAT Bluefin Tuna Data Preparatory Meeting (Madrid, Spain - June 14 to19, 2010). | Anonymous |
| SCRS/2010/015 | Report of the 2010 ICCAT <br> Mediterranean Swordfish Stock <br> Assessment Meeting (Madrid, Spain June 28 to July 2, 2010). | Anonymous |
| SCRS/2010/016 | Report of the 2010 ICCAT <br> Mediterranean Albacore Data <br> Preparatory Meeting (Madrid, Spain June 28-July 2, 2010). | Anonymous |
| SCRS/2010/017 | Report of the 2010 ICCAT Bigeye Tuna Stock Assessment Session (Pasaia, Gipuzkoa, Spain - July 5 to 9, 2010). | Anonymous |
| SCRS/2010/018 | Report of the 2010 ICCAT Bluefin Tuna Stock Assessment Session (Madrid, Spain - September 6 to 12, 2010). | Anonymous |
| SCRS/2010/019 | An evaluation of changes in stock productivity and consequences for management. An example based on North Atlantic albacore (Thunnus alalunga). | Kell, L.T and Fromentin, J.M. |
| SCRS/2010/020 | Standardized catch rates for blue marlin (Makaira nigricans) from the Venezuelan pelagic longline fishery off the Caribbean Sea and the western central Atlantic: Period 1991-2009. | Arocha, F. and Ortiz, M. |
| SCRS/2010/021 | Catch rates for blue marlin (Makaira nigricans) from the small scale fishery off la Guaira, Venezuela: Period 19912009. | Arocha, F., Medina, M., Bárrios, A., Ortiz, M. and Marcano, L.A. |
| SCRS/2010/022 | Bigeye (Thunnus obesus) by-catch estimates from the albacore Spanish surface fishery in the North East Atlantic: years 2007-2009. | Ortiz de Zárate, V., Perez, B. and Ruiz, M. |

| SCRS/2010/023 | The Precautionary Approach to fisheries management: How this is taken into account by tuna regional fisheries management organisations (RFMOs). | de Bruyn, P., Murua, H and Aranda, M. |
| :---: | :---: | :---: |
| SCRS/2010/024 | Preliminary evaluation of alternative stock-recruitment models for estimating benchmarks of tuna-like species. Application to the eastern bluefin tuna (Thunnus thynnus) stock and recruitment data | Ortiz, M. |
| SCRS/2010/025 | Incorporation of scientific uncertainty to define precautionary management targets: a case study of Atlantic bigeye tuna. | Cass-Caley, S. |
| SCRS/2010/026 | Construction and examination of Stock Synthesis Assessment Model for bigeye tuna. | Schirripa, M. |

## OPENING ADDRESS BY DRISS MESKI, ICCAT EXECUTIVE SECRETARY

## Mr. Chairman, Distinguished Delegates, Ladies and Gentlemen:

You scientists are here once again to carry out long discussions initiated many months ago. I would like to take this opportunity to express to you, on behalf of the Commission, my wholehearted appreciation for your sacrifices and the courage which you exemplify each time you are requested. I cannot let this occasion pass without congratulating you for your efforts and your devotion to the cause of ICCAT and to your Chairman, Dr. Jerry Scott, who has made the work of our Commission a model to follow at the international level.

As usual, the city of Madrid which the majority of you know better than I do welcomes you. I would like to thank the Spanish authorities at all levels for their constant support of our Commission.

Mr. Chairman, Ladies and Gentlemen, I too would like to express the feeling of frustration and dismay that I have heard here and from regional and international authorities in charge of fishing.

Reference is always to ICCAT as a regional organization that is not modern and whose work is not being done in terms good management of the tuna resources. This surprises me when I see the intensity of the work of your Committee and the deep respect the Commission has for your work. It is true that for some species there has been a discrepancy between the recommendations from the SCRS and those from the Commission, but I believe that this discordance is past. I hope that the deliberations of your Committee provide all information needed to respond to the concerns expressed by international public opinion and that our Commission takes these into consideration, and refutes any prejudgment on the effectiveness of our organization.

My best wishes to you and may you enjoy a pleasant stay in Madrid.

## WORK PLANS OF THE SPECIES GROUPS FOR 2011

## Tropical Tunas Work Plan for 2011

No stock assessment(s) are planned for yellowfin tuna, bigeye tuna or skipjack tuna in 2011. None-the-less, it is necessary to update the fishery indicators for all three stocks in 2011. Noting the on-going difficulties posed by inadequacies in the data for the eastern tropical purse seine fisheries, in particular the Ghanaian statistics as well as the accounting of "faux poisson", the Group decided to set a priority on improving these data prior to revisiting analyses of management measures (such as closed areas and gear restrictions) or conducting stock assessments.

The Group plans to address this problem in two phases. First, a working group shall be formed to examine the available Ghanaian data, sampling and reporting programs in detail, as well as the relevant programs in the Ivory Coast for estimaating "faux poisson". This group, which should be kept relatively small to enable efficient collaboration of these evaluations, should consist of experts in the eastern tropical purse seine fisheries, including operations, data collection and processing. Scientists from Ghana and the EU must be involved, as should scientist(s) from the Côte d'Ivoire (to advise on "faux poisson" estimation), and other scientists with relevant expertise (including those from countries without eastern tropical PS fisheries, to provide a broad perspective). This small working group will be tasked with gaining a thorough understanding of the data, data collection, processing and reporting systems, in order to provide guidance and initial recommendations to the Group.

The Group decided that in order to conduct a thorough review of the findings of the small group, and develop a clear plan for future data collection, processing and reporting as well as potential historical revisions that could be adopted by the Committee, the second phase of this process should be a meeting of the Tropical Tunas Working Group held after the first phase is complete. This tentative agenda for this meeting is shown in Addendum 1 to Appendix 5.

It is expected that, although initial work for phase 1 may be conducted by correspondence, it will necessitate a meeting to review the data and procedures and to formulate findings. This meeting should be conducted early enough in the year to allow time for the phase 2 meeting of the Work Group (to finalize analyses and advice) to take place.

In addition, the Tropical Tunas work plan envisions proceeding with a large-scale tagging program (Addendum 2 to Appendix 5) in 2011 and beyond.

## Albacore North and South Atlantic and Mediterranean Stocks Work Plan for 2011

## Overview

The results from the assessment of North Atlantic albacore carried out in 2009 (SCRS/2009/015, Anon., 2010) modelling data up to 2007, could indicate that the stock is being overfished since the mid-1980s. Sources of uncertainties identified in the data when analyzing the status of the stock and used to draw conclusions on the status of the stock are a continuous concern in the Group.

The results from the July 2007 assessment of the South Atlantic albacore stock and modelling data up to 2005 are still considered to adequately characterize the status of this stock (SCRS/2007/015, Anon. 2008). Nevertheless, there is a recommendation from the Commission to assess the southern stock in 2011 [Rec. 07-03].

This year, in July, following the recommendations of the Commission in 2009, a Mediterranean Albacore Data Preparatory Meeting was held, although no assessment was done. Complete information is given in SCI-032 report.

## North Atlantic Stock Proposed Work Plan for 2011

Given the uncertainty on the results obtain in the last assessment done which analyzed data to 2007, the Group reiterates the need to carry out a comprehensive research program (SCRS/2010/155 and Annex SCRS/2010/155) that had been presented for support by the Contracting Parties and allocate funds to this purpose. Some partial research is being carried out through national funding. The main research objectives identified by the Albacore Species Group are:

1) Improved knowledge of the population dynamics of albacore in the North Atlantic.
2) Improved understanding of the interactions between the biological and ecological processes of the albacore stock and the fisheries.
3) Reduced uncertainty in stock assessment, e.g. growth modelling and modelling of indices of abundance that take into account migrations based on variable environmental conditions and targeting.
4) The provision of robust management strategies for the sustainable exploitation of the stock at MSY that take into account social and economic objectives.

Meanwhile for 2011 it is recommended that basic indicators be developed for the northern stock to improve the reporting rate of Task II data (catch, effort and size) according to the required standards of ICCAT for the surface and longline fisheries and to produce standardized catch rates from all gears fishing northern albacore.

The Committee endorses the proposed research plan in SCRS/10/155 and Addendum 3 to Appendix 5 and recommends funding be initiated in 2011 or as soon as possible.

## South Atlantic Stock Proposed Work Plan for 2011

Assuming the recommendation to have an assessment of the southern stock in 2011, the following tasks shall be accomplished and be available to ICCAT at least of two weeks before the assessment session:

- Complete and revised Task I data for the surface (mainly baitboats) and longline fleets.
- Complete and revised Task II data (catch, effort and size) for the major surface and longline fleets.
- Time series of standardized CPUE for the main surface and longline fleets exploiting the southern stock.
- Produce the catch-at-age (CAA) for the southern stock.
- Any new information concerning biological parameters to be used in the modelling of the stock should be provided to Group.
- Revision of the model to be applied in the assessment and well documented code is required in advance of the assessment.
- Coordination between national scientists and the ICCAT Secretariat is planned before the assessment and a website will be set up to facilitate data provision and communication among participants.

## Mediterranean Albacore Stock Proposed Work Plan for 2011

There are a number of statistics and research recommendations listed by the Albacore Working Group in the Report of the 2010 ICCAT Mediterranean Data Preparatory Meeting [SCI-032] in order to carry out the assessment of this stock in 2011:

- CPCs are urged make an effort to provide all Task I and Task II data for all fleets according to ICCAT's required statistical format at least one month before the assessment meeting. Also, efforts should be addressed to provide the revision of both Task I and Task II data available in ICCAT database according to the problems identified.
- Standardized catch rates for the major longline fleets and surface fisheries and also for the sport catches should be developed. The data should be available at least two weeks before the assessment meeting.
- Considering that biological data have likely been collected in different data collection programs (e.g. $\mathrm{EU} / \mathrm{DCR}$ ), it is recommended that a concerted effort be made to consolidate these data in an appropriate form for analyses.

## Bluefin Tuna Work Plan

The Bluefin Tuna Species Group reiterates the fact that, unless substantial improvements are made in the catch and effort statistics or new information on key issues is available, there is little scientific need to perform a stock assessment every two years. Furthermore, any change in exploitation or management will take several years to have a detectable effect on bluefin tuna biomass because bluefin is a long lived species. Furthermore, the Eastern fisheries are currently adapting to new management measures (i.e. [Rec. 08-05] - [Rec. 09-06]), so that again it will take a few years to fully evaluate the implications of these measures on the stock. Therefore, the bluefin tuna Species Group does not plan to conduct any new comprehensive assessment before 2013.

In the interim, the bluefin tuna Species Group plans to focus efforts on the research activities outlined within the Bluefin Research Plan, such as large-scale tagging, aerial surveys, otolith microconstituent analyses, genetics and reproductive biology. This interim will further give the opportunity to the Bluefin Tuna Species Group to improve models for evaluating bluefin dynamics and status (which can hardly be done during a stock assessment year), including forecasting and operating models that incorporate spatial variability and mixing as an example. The overall approach would allow the bluefin tuna Species Group focus on important or novel issues regarding data and models which will thus improve the quality and credibility of future assessments.

Therefore, a first Working Group is planned in 2011(April or May) to review potential alternative approaches (statistical models, MSE, etc.) that could better take into account uncertainties in the data. During 2011 and 2012, the candidate models would be simulation tested. Then, a data preparatory meeting would be held in 2012 to prepare for the stock assessment session. If the Commission requires an assessment before 2013, the Committee would be unable to develop new quantitative approaches or to fully use novel information from the GBYP and could only update past assessments with standard tools (i.e. VPA).

## Billfish Work Plan

## Summary

The Working Group initially proposed to conduct a Data Preparatory Meeting in 2009 and the next assessment of blue marlin and white marlin in 2010. These meetings were later postponed to 2010 and 2011 to better accommodate the 2009 Atlantic sailfish stock assessment. Due to genetic analyses and model projections results reported by Beerkircher et al. (2010), historical catches of white marlin may also inadvertently reflect significant numbers of roundscale spearfish and even longbill spearfish. For this reason, the working group felt that a white marlin assessment would not be possible in 2011, until this problem is resolved.

In 2009 the Working Group proposed to conduct the assessment through a three stage process:

1) Hold a data preparatory meeting for blue marlin in the first half of 2010 to produce catch estimates, update biological parameters, and estimate relative abundance indices for blue marlin which was successfully completed.
2) Conduct an assessment of blue marlin in 2011 and develop white marlin catch estimates, including a major effort to separate catches of roundscale spearfish (and other spearfish) from white marlin catches to the extent possible. We anticipate this effort will require an investment of funds by ICCAT through the ERPBF to accelerate the genetic analyses currently being conducted on this topic. Update biological parameters and estimate relative indices of abundance for white marlin if possible. Data in support of the blue marlin assessment and white marlin data preparatory meeting evaluation must be available at least 2 weeks in advance (Task I and Task II, including any revisions to historical time series, through 2009, submission of more recent data is also encouraged, but not required) of the assessment meeting.
3) Conduct an assessment of white marlin stocks in 2012.

## Background

The last stock assessments for blue marlin and white marlin were conducted in 2006. No assessments have ever been conducted on spearfishes (Tetrapturus spp.). During 2009 the Working Group conducted the first successful assessments for western and eastern Atlantic sailfish stocks.

## Work completed in 2010

The data preparatory meeting for blue marlin was conducted in 2010. In it the group analyzed basic information (T1NC, T1FC, T2CE, and T2SZ), revisions and new data reported during the meeting were incorporated into the ICCAT database. Size information was analyzed in detail for its potential use in integrated assessment models. Disaggregation of reported catches such as unclassified billfish and filling the gaps of the time series for fleets that had incomplete historical reports were conducted. Several relative abundance indices were presented at the meeting, and three additional indices were generated during the meeting. Importantly, the working group initiated procedures for the first time to incorporate habitat compression phenonema (Prince et al. 2010) into the assessment process by standardizing CPUE's for blue marlin caught inside and outside the Atlantic compression area from three offshore LL fleets separately.

Historical catch estimates of blue marlin from artisanal fleets with FADs from the Caribbean Sea were calculated. The estimates obtained by the Working Group during the meeting substituted the current blue marlin catch data in Task I for this fishery.

Progress was made in estimating spatial and temporal proportions of roundscale spearfish in relation to white marlin from observer program sets of fishing data in the Caribbean Sea and adjacent waters of the Atlantic.

Progress continues to be made on the age and growth of blue marlin, sailfish and longbill spearfish.
Progress continues to be made on sailfish reproduction off the West Africa and Atlantic coast of South America.

## Proposed work for 2011

- Conduct a blue marlin stock assessment including the estimation of reference points (see recommendations No. 3, 4, and 5 below)
- Provide updates of age and growth of blue marlin (see Recommendation No. 2).
- And update management recommendations.

To prepare for a white marlin assessment in 2012; the following tasks are scheduled or recommended:

1) Accelerate the retrospective genetic analyses to separate landings of white marlins from spearfishes Tetraptururs spp. in historical data.
2) Expand sampling program for the collection of tissues of spearfish and white marlin in:
2.1 West Africa (Senegal, Ghana, Côte d'Ivoire, Sao Tomé and possibly Gabon.
2.2 Chinese Taipei vessels landing in Trinidad and Tobago (Port of Spain), Uruguay (Montevideo) and possibly South Africa (Cape Town).
2.3 Continue sampling in longline vessels from United States, Venezuela, Brazil, Uruguay and Spain.
3) Provide spatial and temporal proportion of roundscale spearfish in relation to white marlin.
4) Update biological parameters (including age and growth) and estimate relative abundance indices for white marlin including those from small scale fisheries that target billfish species.
5) Continue to support the improvement of biological sampling of all billfish species.

## Recommendations

1) The Working Group recommended the need to stress that CPC's should report Task I and Task II for intersessional meetings by the deadlines provided by the Secretariat (two weeks in advance of the intersessional or 31 July, whichever is earlier).
2) The Working Group recommended that anal spine sections and ring measurements be examined to identify and exclude "faux anneau" (false annual rings), and that authors of this work make use of the work by Prince et al. (1991) to "anchor" the early growth estimates obtained from spine sections.
3) The Working Group recommended that the trend analysis conducted in the 2006 blue marlin stock assessment be updated in the 2011 stock assessment meeting.
4) The Working Group recommended that surplus production models conducted in the 2000 blue marlin stock assessment be updated in the 2011 stock assessment meeting.
5) The Working Group recommended to establish a protocol (web based) to continue progressing with the application of a statistically integrated assessment model that would take into consideration, seasonal catch, effort, size information for all gears, and the new geographical stratification proposed during the blue marlin data preparatory meeting.
6) The Working Group recommends that the genetic analysis proposal (Appendix 6) be considered at the next SCRS species group meeting.
7) The Working Group recommends that the ICCAT Manual be updated to consider the misidentification problems between roundscale spearfish, longbill spearfish and white marlin.
8) The Working Group recommends the preparation of identification sheets for all species of billfish, similar to those being prepared for sharks and small tunas.
9) In noting that estimation of relative abundance indices is always best done at the highest spatio-temporal resolution warranted by the available data, the Working Group recommends that all CPCs, and especially those that have important catches of blue marlin, provide updated relative abundance indices obtained from such high resolution CPUE data.
10) The Working Group should conduct an analysis on gaps of reported catches from various CPC's by considering Task I and Task II data and the methods used during the sailfish data preparatory meeting in 2008 (Anon. 2009).
11) The Working Group recommends that the quality of conventional tags being distributed by ICCAT be improved, as there is significant evidence of tag shedding.
12) In order to improve the information on all billfish: continue the efforts of reviewing catch estimates, especially for those countries that are known to land billfish but do not report it to ICCAT.

## Swordfish Work Plan

## Background

The last assessments for North and South Atlantic swordfish were conducted in 2009. The next assessment should take place no sooner than 2012.

For the Mediterranean stock, the last assessment was conducted in 2010. The next assessment should take place not before 2013 except if negative indicators arise from the fisheries.

## Proposed work

## North and South Atlantic

A list of recommended work has been provided in the Report of the 2009 Swordfish Stock Assessment Session. Among those recommendations, the following were identified as high priority areas where continued efforts are required:

Data Preparatory and Methods Meeting. Due to time constraints, recent sessions of the swordfish Working Group have provided assessments that have updated past results using methods and approaches available at the time. The Group recognizes that newer stock assessment approaches are now available which more fully incorporate biological data and provide more complete representations of uncertainties in stock status. To allow the Group time to explore the new approaches and to assemble the data in advance of the stock assessment session, it is recommended that a working session of five days duration be convened prior to the next assessment. The meeting could be convened in the year before the next assessment (next assessment proposed for 2013).

Catch. All countries catching swordfish (directed or by-catch) should report catch, catch-at-size (by sex) and effort statistics by a small an area as possible, and by month. These data must be reported by the ICCAT deadlines, even when no analytical stock assessment is scheduled. Historical data should also be provided.

CPUE Series. It is recommended that given the similarity between part of the Brazilian and Uruguayan swordfish fishing fleets and taking into account that the CPUE standardization studies of both fleets submitted at the meeting differ in their methods and results it would be desirable that scientists from Brazil and Uruguay hold inter-sessional meetings to deal with the standardization of CPUE series and processing of data from their respective fleets.

Assignment of ages. The computer codes used for ageing swordfish in the Atlantic should be updated. The new sex-specific growth curves (Arocha et al. 2003) should be incorporated, and its impact in terms of the catch-atage estimation, as well as its consistency with the tagging data should be evaluated before a new set of growth curves is formally adopted by the Group.

Discards. Information on the number of undersized fish caught, and the numbers discarded dead and released alive should be reported so that the effect of discarding and releasing can be fully included in the stock assessment. Observer sampling should be sufficient to quantify discarding in all months and areas in both the swordfish directed fisheries and the tuna fisheries that take swordfish as by-catch. Studies should be conducted to improve estimation of discards and to identify methods that would reduce discard mortality of swordfish. Studies should also be conducted to estimate the subsequent mortality of swordfish discarded alive; these are particularly important given the level of discarding due to the minimum size regulatory recommendation.

Target species. All fleets should record detailed information on log records to quantify which species or species group is being targeted. Compilation of detailed gear characteristics and fishing strategy information (including time of set) are very strongly recommended in order to improve CPUE standardization. The recommendations made by the 2002 meeting of the Working Group on Methods for looking at diagnostics in this context should be followed. The Group recommended the investigation of alternative forms of analyses in the south that deal with both the by-catch and target patterns, such as age- and spatially-structured models.

Recruitment Indices. The Group's ability to forecast stock status within the VPA is contingent on the availability of reliable indices of abundance at the youngest ages. For example, age- 1 indices of abundance are only available up to 2001. Countries that have traditionally provided such indices should update their time series, as a matter of high priority. This research should be supported at the Contracting Party level.

Assessment Methods. The Swordfish Species Groups (Atlantic North and South and Mediterranean) shall develop a research plan to address key data deficiencies associated with the stock assessments, and to investigate new stock assessment methodologies. The Plan should be tabled for discussion during the 2011 SCRS Plenary and include cost estimates.

## Mediterranean

Catch and effort. All countries catching swordfish (directed or by-catch) should report catch, catch-at-size (by sex) and effort statistics by as small an area as possible (5-degree rectangles for longline, and 1-degree rectangles for other gears), and by month. It is recommended that at least the order of magnitude of unreported catches and discards be estimated. The Group noted that it is important to collect size data together with the catch and effort data to provide meaningful CPUEs by age.

Gear selectivity studies. Although some work has been already done, further research on gear design and use is encouraged in order to minimize catch of age-0 swordfish and increase yield and spawning biomass per recruit from this fishery.

Stock mixing and management boundaries. Considering differences in the catch and CPUE patterns between different Mediterranean fisheries, further research, including tagging investigations, in defining temporal variations in the spatial distribution pattern of the stock will help to improve stock assessment and management.

## Small Tunas Work Plan

Continue improving catch statistics through the distribution of the small tunas species identification sheets and with the support of ICCAT data improvement projects.

Continue studies on stock structure and species distribution.

Review of the small tuna species for their inclusion in the consolidated ICCAT official list of species.
Develop simple indicators of stock sustainability such as proportion of juveniles within the catch and statistical trends in catch histories.

Collaborate, as much as possible, with CRFM on blackfin tuna assessment that will be held in 2011.
Follow progress of blackfin tuna aquaculture experiments being performed the University of Miami (United States).

## Sharks Work Plan

## General comments

In the porbeagle assessment carried out in June 2009, some of the problems already identified in past assessment meetings still persisted. Of concern are the lack of total or partial Task I and Task II data, standardized CPUE series for some fleets, and the lack of biological information, which results in uncertainties in the assessment. Further, as occurred on other occasions, the absence of scientists from the Parties that catch this species, limits the possibilities of the assessment. As was expressed last year, this situation is not exclusive to this Group and raises a problem that should be resolved through the firm commitment of the Parties.

## Work Plan

Develop standardized CPUE series for future assessments, for as many species as possible, for all the major fleets that exploit shark species as target or by-catch in the North and South Atlantic. To do this, collaboration among the Parties that leads to an exchange of information should be generated, and conventions or specific projects that could be financed by ICCAT funds for capacity building should be encouraged.

A more extensive and improved database should be developed to update the Ecological Risk Assessment (ERA) carried out in 2008. In this sense, the scientists are urged to carry out work on the life history of the shark species and to provide the Sharks Species Group with all the available information for their respective countries to be incorporated in future assessments. The information on fishing operations and on the status, availability and size of the individuals caught (collected from the observer programs) is essential to estimate vulnerability and to thus generate a specific ERA for each fleet.

Carry out a Data Preparatory meeting in 2011 to generate the information needed to conduct an Ecological Risk Assessment (ERA) for as many species as possible in 2012.

In this respect, the possibility of developing a program for sharks such as those for other species, would allow using funds that facilitate research on such a diverse group of species.

Electronic tagging programs for shark stocks should be initiated or encouraged as a means to obtain fisheriesindependent data and information related to habitat.

Support ICES in the Data Preparatory meeting for the porbeagle assessment in 2011.

## Methods Work Plan

The plans for 2011 include:

## Primary topics for 2011:

- Conducting Meta-analysis for investigation of key parameters (e.g. steepness, r, K, etc) in order to reduce uncertainty, assess parameter influence on assessment outputs and improve estimates.
- The Group plans to conduct investigation into thresholds, reference points, and the use of HCRs to manage risk of exceeding key reference points.

## Secondary topics - long term:

- Important issues raised during the 2010 meeting have resulted in the need to investigate plus-group dynamics and the implications of different calculations and assumption.
- To investigate techniques to weight assessment models for those cases where the outputs of more than one model are combined to provide advice.
- Lastly the Group would like to conduct some preliminary investigations into Ecosystem models in terms of data requirements as well as suitable models for use by the Commission Working Groups.

## Ecosystems Work Plan for 2011

An inter-sessional meeting is envisaged for 2011 (not before May so as to allow enough time to complete the analyses).

The Sub-Committee on Ecosystems encourages scientists to continue providing available detailed information about interactions with by-catch species that may allow quantification of total removals. Moreover, it considers essential to gain information on basic knowledge about the ecosystem (e.g. relationship between tunas, their prey, their competitors, the environment, etc.) in order to facilitate the development of ecosystem models in the Atlantic. The Sub-Committee also suggests continuing discussions on ecosystem indicators (e.g. biodiversity indicators, size based indicators, trophodynamic indicators, etc.) that would be useful to monitor in the SCRS context. Finally, the Subcommittee encourages scientists to continue providing results on research about the impacts of mitigation measures on catch rates of by-catch and target species.

A tentative Agenda for the 2011 inter-sessional meeting would be:

- Review of new information regarding ecosystems
- Ecosystem modeling approaches
- Ecosystem indicators useful for the SCRS
- Research on by-catch mitigation measures
- Other matters
- Recommendations

Addendum 1 to Appendix 5

## Revision of Ghanaian Statistics

The Working Group on the Revision of Ghanaian Statistics focuses on two objectives:

- Analyze Ghanaian Task I and Task II (including size data), specifically in a comparative approach with the EU purse seine fishery operating in the same fishing grounds.
- Propose a sampling scheme as close as possible as the protocol used in the EU fishery and rebuilding past Ghanaian statistics, if necessary, based on the comparative analysis.

## Tentative Agenda

1. Opening
2. Historical overview
2.1 Summarized background information on the different data collection and processing systems used before the JDIP started its contribution to the improvement of statistics (Ghanaian scientist)
2.2 Information on the Ghanaian data (Task I and Task II data) existing in the ICCAT database (Secretariat)
3. Yearly Task I data
3.1 Total catch by species and by gear
3.1.1 Source of data: Skipper's declaration, canneries data, logbooks (including description of information provided and coverage) (Ghanaian scientist)
3.1.2 Cross-checking and other validation process (Ghanaian scientist)
3.1.3 Potential problems: Landings in Abidjan, transshipments (at sea and in foreign ports), BB-PS collaboration, "faux poissons", potential under reporting of total catches
3.1.4 Species composition (in connection with 4 and 5)
3.2 Fleet (Ghanaian scientist)
3.2.1 Source of data
3.2.2 Updating process
4. Yearly Task II: Catch and effort data
4.1 Logbooks system: coverage, validation process, processing system (Ghanaian scientist)
4.1.1 Data available in the ICCAT data base: summary of information received including description, format in which the information was received and analyses conducted by the Secretariat (Secretariat)
4.1.2 Problems related with the logbooks system and possible improvements
4.1.3 Species composition sampling and comparison between EU and Ghana yearly species composition
4.2 Observers program: coverage, data processing (Ghanaian scientist)
4.2.1 Data available in the ICCAT data base: summary of information received including description, the format in which the information was received and the analyses conducted by the Secretariat (Secretariat)
4.2.2 Problems related with the observer's program system and possible improvements
5. Yearly Task II: Sampling system and estimated catch at size
5.1 Species and size sampling in Tema:
5.1.1 Description of sampling scheme, coverage (Ghanaian scientist)
5.1.2 Data processing: from size samples to catch at size. Data reported to ICCAT. (Ghanaian scientistSecretariat)
5.1.3 Comparison between estimated PS CAS and cannery data
5.1.4 Comparison between EU and Ghana yearly catch at size by species
5.2 Sampling in Abidjan:
5.2.1 Description of sampling scheme, coverage (Ghanaian scientist)
5.2.2 Data processing. Data reported to ICCAT. (Ghanaian scientist-Secretariat)
5.3 Problems related with sampling and possible improvements
5.3.1 Potential bias: apparent lack of large fish in the samples. Comparative analyses with EU samples, canneries information and other possible sources should be done in advance to the meeting (EU scientists-Ghanaian scientists)
5.3.2 Suggested improvements in historical data and recommendations for future sampling scheme
6. Recommendations
7. Other matters

## Addendum 2 to Appendix 5

## A Proposal for an Atlantic Ocean Tropical Tuna Tagging Program (AOTTP)

(Developed by the Tropical Tuna Species Group of SCRS)

#### Abstract

Since there is no independent fishery information for tuna stock assessments, the objective of this document is to present a proposal for a large scale tropical tuna tagging program in the Atlantic. Such program is fundamental to

improve the estimates of key-parameters of population dynamic, to reduce stock assessment uncertainties and to gauge the effectiveness of different fisheries management options. For all of these reasons, we propose an Atlantic Ocean Tropical Tuna Tagging Program (AOTTP) for a duration of 5 years and a total cost close to $11,400,000$ Euros; including 3 bait boats chartering, the recruitment of a specific tagging team, and the associated costs related to tagging operations (tags, rewards, publicity, etc). The technical objective of this program is the tagging of 150.000 fishes of the 3 main tropical tuna species at different sizes with conventional tags and 300 fishes with archival tags.

## Introduction

Stock assessments of Atlantic tropical tunas are hampered due to uncertainties in several population, life history and biological parameters. These include such important considerations as stock structure, natural mortality at age, sex-specific growth and sex-specific natural mortality (which may be particularly important for yellowfin tuna), survival rates after release, migratory patterns and residence times, the influence of FADs and oceanographic features on behavior and productivity, the exploitation rates suffered by the stocks and the extend of fishery interactions between fleets. In contrast to many other fisheries where direct estimates from fisheryindependent sources, such as surveys, can be combined with fishery data, tropical tuna assessments are based only on fishery-dependent data. As a consequence, tagging information (from both conventional and electronic tags) is very relevant (1) in stock status diagnosis and (2) in evaluating fisheries management options, such as time-closure areas, minimum sizes and catch quotas as they provide additional information partly independent of fishery.

It must be stressed than different tagging programs have been conducted in the past in the Atlantic tropical Ocean. However, these programs were implemented during discontinuous periods of time, in specific areas (i.e., mainly in the Eastern Atlantic), in general within a monospecific assessment framework (the different ICCAT "Year Programs") and, even under the ICCAT coordination, by different national tagging teams. In most cases, the heterogeneous and limited results have had very little impact on stock assessments done by ICCAT scientists on Atlantic tropical tunas.

The Committee recommends that a large scale comprehensive tagging program, covering the entire distribution of the 3 species of tropical tunas (yellowfin, skipjack and bigeye), be initiated as soon as possible (see Figure 1, at the end of the document for the spatial distribution of catches).

The objectives of this document are to:

1. highlight the links between stock status diagnosis, fisheries management options, and the expected outputs from a large-scale tagging program throughout both sides of Atlantic Ocean;
2. provide an overview of the organizational and logistical requirements for such a large scale successful program and,
3. provide an indicative budget.

## Expected outputs of a large tagging program

The program is expected to have a time-duration of five years, including initial phases and a period allowing for tag recovery.

The broad geographical coverage and a three-year tagging period are required to determine:

- the extent of movements of the three main tropical tunas species (yellowfin, skipjack and bigeye) throughout the entire Atlantic Ocean and its potential effect on the revision of the present stock structure hypothesis;
- the recent levels of exploitation across the entire range of the stocks and to reduce uncertainties in parameter estimates (with special attention to integrated stock assessment models that can potentially incorporate capture-recaptures data);
- the improvement of age- and area-specific population parameters (e.g., natural mortality by age/size, movement rates, sex- and area- specific growth etc) as well as their geographical and inter-annual variability (for instance by comparison with results obtained during historical tagging programs.)
- the level of interaction between surface and longline fisheries throughout the Atlantic Ocean; specifically for bigeye and yellowfin tuna (assuming an improvement of the recovery rate of tags on longliners);
- the interactions between the 3 major tuna species in terms of a multispecies approach of stock assessment, their habitat uses and their respective integration in habitat based model;
- the effect of the use of FADs by purse seiner in the Gulf of Guinea on the movement patterns and biology of skipjack (at all ages) and of juveniles bigeye and yellowfin, as in the associated school fishing technique in some bait boat fisheries (the "ecological trap" hypothesis), as well as the residence time of tunas around seamounts and other features;
- characterizing and quantifying the effects of environmental factors on the movements and behaviors of each species, which may be size-dependent;
- the analysis of survival rates for released fish in case of size-catch regulation.

Electronic (including archival) tags can be combined with conventional tags to provide valuable information in addressing all of these points. They will be particularly useful in evaluating the influences of environmental factors, as well as in providing critical data for developing management measures for multispecies fisheries (species-protected time areas, size-quota by time-area strata, etc).

Based on previous tagging programs in the Atlantic, it must be stressed that the majority of released fish were individuals less than three years old, principally because these age classes are easily caught and tagged in surface schools by bait boats. All sizes and ages of skipjack can easily be tagged by such method, but as one of the core objectives of the proposed program is to provide estimates of the main biological parameters over the entire life cycle of yellowfin and bigeye, the program will tag a wide a range of sizes/ages of these 2 species, using a variety of tagging platforms across the Atlantic Ocean. Another goal of this tagging program would be to tag similar numbers of the 3 species, keeping in mind that bigeye and yellowfin are more difficult to tag in large numbers: in order to reach this target, the tagging program will include the use of the "associated school" fishing technique developed by the Dakar baitboat fishery that permits tagging a high percentage of bigeye and yellowfin. This tagging mode will require conducting some of the tagging cruises with 2 tagging vessels working in full cooperation (following the technique employed during commercial operations, wherein the associated school is "handed off" to the next vessel).

## Organization and logistic

In light of the success showed by the massive tagging program recently conducted by the IOTC in the Indian Ocean, similar structure in terms of coordination all the stages of this tagging program, constitution of a specific tagging team in charge of the logistics, tagging operations, publicity, recovery of tags in landing ports, data entry and data validation, etc, is highly recommended. There is no doubt that such an approach would provide a wide range of high quality results that cannot be obtained by the traditional ICCAT tagging programs left to heterogeneous tagging teams with an insufficient ICCAT role.

In contrast to historic ICCAT tagging programs devoted mainly to one species, and in general implemented in the Eastern Atlantic, for the reasons mentioned previously, tagging experiments must be developed in the entire Atlantic and under a multispecies framework. The number of releases by spatial-temporal strata should be determined through preliminary analyses or simulation studies (see below) as part of a comprehensive tagging study design phase. Candidate tagging sites for tagging surveys can be easily identified in the Atlantic, where bait boat fisheries or bait boats like vessels have been operating, such as: Azores, Madeira, Morocco, Canary Islands, Mauritania, Senegal, Cape Verde Islands, Ghana, Sao Tome, Gabon, Angola, Cuba, Venezuela, Brazil. Furthermore, the various PIRATA buoys anchored in various place of the Eastern and Western equatorial Atlantic may also offer an interesting potential to tag bigeye tunas as well as other tuna species. With the aim of targeting other age/size classes, additional tagging operations should be conducted from other fisheries, such as recreational fisheries (United States, Venezuela, Mexico, Antillean islands, Brazil), small-scale fisheries (French Antilles), small longliners or from scientific vessels (Uruguay and United States). In the case of candidates tagging sites where tagging has never been conducted yet, the feasibility of the tagging experiments should be explored. It must be stressed that the availability of live bait is always a severe limiting factor when planning such tagging programs. Nevertheless in the Atlantic, there is a good knowledge of many potential strata where good live bait can be caught by the tagging vessel (if necessary, in cooperation with artisanal fisheries that are frequently targeting these coastal resources).

As part of this process, simulation modeling of tagging operations should be conducted as soon as possible in order to improve the designs in operational tagging surveys, and in order to reduce uncertainties in parameter estimates (with special focus on integrated stock assessment models). Based on other type of information (e.g., assumed trajectory of FADs) potential time-closure areas should be accounted for in order to design future
tagging experiments useful to evaluate the effectiveness of protected area to reduce the fishing mortality exerted on juveniles (i.e., to evaluate the residence time within protected areas and movement rates between the freeaccess areas and the protected area).

Given the urgent requirement for stock assessments and potential regulatory measures, we propose to begin in 2011 a number of small scale exploratory tagging and promotional pilot projects, as precursors to the main program, as well as a meeting devoted to the design the plan and budget of the full scale tagging experiments.

Given the ocean-basin scale of the field work, the tagging program will need to be a multi-national effort. All ICCAT members and Cooperating non-Contracting Parties would be approached to assist with the program, including with respect to the granting of access to the tagging cruises in the various EEZs, with the publicity campaign concerning tag recoveries and reporting, the recovery of tags and the and the initial validation of the reported tags. However, the ICCAT should take the lead role of program coordination through the formation of a special Tagging Program staff unit that would be fully responsible of most steps in the tagging program (a framework similar to the recent IOTTP ran by the IOTC).

The unit would comprise the following staff:

1. Chief Scientist - Co-ordinate the program, senior staff supervision, data analyses, reporting.
2. Field Coordinator, - Responsible for field logistics, tagging protocols, supervision of tagging staff.
3. 4 Senior Tagging technicians.
4. Promotions/Liaison/support officer
5. 1 administrator and 1 secretary
6. 3 field technicians in the main landing ports in charge of tag recoveries.

Ad hoc support by in-country scientist experts in tagging would also be very useful and could be used instead of the Tagging Staff in some components of the tagging program. The program should ensure that all taggers have a full tagging efficiency, reducing as much as possible the immediate tagging mortality or loss of tags. The use of the same bait boat and of the same Tagging Staff during most tagging operations, a method used by the IOTC, might be considered.

From past experience in historic tagging programs coordinated by ICCAT, it was evidenced that many recaptured tags for which data are not validated and corrected at the time of the report are then not usable for the majority of scientific studies. Keeping in mind the costs of a Tagging Program, the validation and the potential correction of recoveries in a short time as well as a detailed report of the released fishes are an important issue in all large Tagging Programs. These activities, and the continuous update of a specific friendly user Tagging data base, are important tasks which justify the recruitment of a Tagging Staff, even if the contributions of national scientists and ICCAT secretariat are essential.

Estimation of tag reporting rates should also be an important target in the tagging program. For estimates of fishing mortality, and to a lesser extent natural mortality estimates, of tagged fish, tagging results need to be representative of mortality rates of the population in general, and estimates of tag-reporting rates for all significant fisheries must be obtained. For purse seine fisheries, this estimate of reporting rates can easily be accomplished by means of a tag-seeding experiment, and a lot of emphasis should be given on doing such a tagseeding experiment before and during the entire tagging program.

The tagging program should also include a wide range of publicity and rewards that are essential in the success of such a large scale program in order to maximize the report of tagged fishes. These publicity actions should, for instance, cover (1) appropriate incentives for the return of tags - attractive cash rewards, caps, t-shirts, etc., (2) Prompt payment of rewards, along with a letter to the tag finder advising full details of the tagged fish, (3) Widespread multilingual publicity regarding the program via tagging posters, (4) ads in local newspapers, radio, TV to advertise special events such as tag lotteries, (5) Regular visits of fisheries officers to unloading ports to personally ensure that the tag return process is functioning smoothly.

## Timetable-Cost and financing plan

The main AOTTP tagging operations would be conducted for a period of 2 years by 3 pole and line vessels, but a number of small scale and exploratory tagging, promotional pilot projects, should be conducted before and during the AOTTP.

Based on a recovery rate assumed close to $20 \%$, it is expected that at least 150.000 tagged fishes with conventional tags would need to be released in order to yield fully significant data, preferably tagging similar percentages of the 3 species. Such a target should easily be reached in the Atlantic Ocean, an area where pole and line vessels have been very active in many areas for more than half a century. In complement, 300 fish will be tagged with Pop-up satellite archival tags (PSATs) to obtain information about habitat used by the different species at different size.

The appended provisional budget is proposed to cover the main framework of the tagging program presently recommended by SCRS.

Figure 1. Average catch by species for the 1990-2003 period.

## North Atlantic Albacore ICCAT Research Program

The Albacore Working Group reiterates the last year proposal of initiate a coordinated, comprehensive research program on North Atlantic albacore to advance knowledge of this stock and provide more accurate scientific advice to the Commission.

The research plan will be focussed on three main research areas: biology and ecology, fisheries data and management advice during four-year period. Each of these main topics includes more detailed research aims as is presented in document $\mathrm{SCRS} / 2010 / 155$. The requested funds to develop this research plan have been estimated in a cost of 4.3 million Euros. The research program will be an opportunity to joint efforts from European scientist from research institutes involved in the albacore fisheries as well as CPC's scientists involved in the research of longline fisheries of North Atlantic albacore.

| Research aim | Feasibility | Priority |
| :---: | :---: | :---: |
| 1. Biology and Ecology | 1 to 4 | 1 to 3 |
| - reproductive biology (maturity, spawning area and season, and sex-ratio) | 2 | 1 |
| - growth (validation, growth modelling by sex) | 1 | 1 |
| - stock structure, genetics | 1 | 1 |
| - natural mortality, conventional tagging (*) | 4 | 3 |
| - habitat and migration ( wintering and feeding areas; horizontal and vertical distribution), electronic tags (*) | 2 | 1 |
| - feeding ecology (isotopes) | 1 | 3 |
| 2. Fishery data <br> - recovery of catch, effort and size from logbooks and increase the number of size samples for longline and surface fleets <br> - efficiency of fleets | 1 | 1 |
| 3. Modelling |  |  |
| - environmental influence on the population dynamics | 2 | 1 |
| - improve relative abundance indices by means of CPUE's analyses | 2 | 1 |
| - improve conversion of catch-at-size into catch-at-age | 2 | 1 |
| - evaluate uncertainties under alternative hypothesis and models used | 1 | 1 |
| - evaluate robustness of alternative management strategies, uncertainties | 1 | 1 |
| Cost estimates in Euros (*) all tagging activities: conventional and electronic |  |  |
| Biology and ecology: estimated budget €3,790.000 |  |  |
| Fishery data: estimated budget €250.000 |  |  |
| Modelling: estimated budget €300.000 |  |  |
| Total estimated cost for a four-year program €4,340.000 |  |  |

## Appendix 6

# ICCAT GBYP ATLANTIC-WIDE BLUEFIN TUNA RESEARCH PROGRAMME 2010 ACTIVITY REPORT FOR 2009-2010 

## 1. Introduction

The Atlantic-wide Bluefin Tuna Research was officially adopted by the SCRS and the Commission in 2008, after a long process. In 2003, as an input of the Working Group established by Rec. 02-11, the SCRS presented the Commission with a research plan to improve knowledge on bluefin tuna, with a special focus on mixing between the two stocks (ICCAT, 2004, Col. Vol. Sci. Pap.ICCAT, 56(3): 987-1003). The various research elements included in this first proposal are still pertinent today, even if some other activities have been included in the following years. During the Marrakech Commission meeting (2008), the SCRS chair met with all the scientists present at the meeting and a detailed proposal was forwarded to the Commission. The proposal was adopted by the Commission in plenary (ICCAT Report 2008-2009 (Part I), Vol. 1: p. 42) and resulted in a first official document, Res.08-06, which covered only the 2004 SCRS proposal but under a broader title. At the same time, the Commission approved the STACFAD Report (ICCAT Report 2008-2009 (Part I), Vol. 1: p. 42), which included the agreement to endorse the Atlantic-wide research programme (ICCAT Report 2008-2009, (Part I), Vol. 1, Appendix 10 to Annex 9: pp. 284-287), establishing three priorities in 2009 (Coordinator, data mining and aerial surveys), other action to be further discussed by SCRS in 2009 and the provision for the programme to be adjusted in the following years taking into account the evolution of its implementation and research needs. The total budget of the programme was estimated at about 19 million Euros in six years, with the engagement of the European Union and some other Contracting Parties to contribute to this programme in 2009 and in the following years.

The SCRS, in 2009, reviewed the updated research proposal submitted by the SCRS Chair, as it was discussed and presented to the Commission at its meeting in 2008 (ICCAT Report 2008-2009 (Part II), Vol. 1: p. 224 and ICCAT Report 2008-2009 (Part II), Vol. 2: pp. 223-224). The SCRS indicated the priorities identified in the 2008 document, as follows:
a) Improve basic data collection;
b) Improve understanding of key biological and ecological processes;
c) Improve assessment models and provision of scientific advice on stock status.

A number of Contracting Parties expressed a willingness to make extra-budgetary contributions to such a programme with a view towards initiation of activities in 2009 related to programme coordination, data mining, aerial surveys, and tagging design studies, with additional research activities to be undertaken in the following years. The first phase costs were set at 750,000 Euros and voluntary contributions sufficient to initiate the year 1 activities were jointly committed by the European Union (80\%), United States, Japan, Canada, Norway, Croatia, Turkey and Chinese Taipei, while Morocco indicated its interest in future contributions. The provision to accept additional contributions from various entities and private institutions or companies was also agreed.

## 2. Coordination activities

The GBYP officially started on 12 October 2009, with the signature of the agreement between the European Community and the ICCAT Secretariat. The GBYP co-ordination full-time activity officially started on 3 March 2010, after hiring the Coordinator (Dr. Antonio Di Natale).

The very first period was devoted to set-up a detailed weekly workplan for 2010 and to organise the coordination structure at the Secretariat, The ICCAT Secretariat set up the administrative structure and the administrative rules were agreed and established, accordingly with the ICCAT system and taking into account the GBYP administrative needs.

During the $1^{\text {st }}$ Phase of the GBYP, the Coordinator participated officially in 15 meetings in various countries. Furthermore, the GBYP Coordinator is providing scientific support to all the national initiatives which are potentially able to increase the effectiveness of the GBYP and its objectives. For this reason, the Steering Committee recommended cooperating with the program on bluefin tuna developed by the NOAA.

The detailed report is available on SCRS/2010/135.

## 3. Steering Committee

The GBYP Steering Committee was nominated on March 13, 2010; the members are the SCRS Chair (Dr. Gerald Scott), the BFT-W Rapporteur (Dr. Clay Porch), the BFT-E Rapporteur (Dr. Jean-Marc Fromentin), the ICCAT Executive Secretary (Mr. Driss Meski), and an external expert (Dr. Tom Polacheck), who kindly accepted this duty.

The Steering Committee's activities included continuous and constant e-mail contacts with the GBYP Coordinator, who provided all the necessary information. The Steering Committee held various meetings (23-24 April 2010; 19 June 2010; 4-5 September 2010; 10-11-12 September 2010; and 30 September 2010) to discuss various aspects of the programme, providing guidance and opinions. During the first two meetings in September, the Steering Committee also provided the detailed plans for Phase 2 and Phase 3 of the GBYP, under two different scenarios, a budget according to the original figure and a reduced minimum budget.

## 4. Aerial surveys

The aerial surveys have the scope to provide fishery independent indices, concerning various components of the stock. The aerial surveys targeting spawning aggregations can potentially provide trends and indices for the spawning stock biomass, while aerial surveys targeting aggregations of juveniles can potentially provide indices for recruitment. Surveys will be conducted with a statistically sound design and for several years in order to get reliable indices.

The budget available (300,000 Euros) for the first phase was not enough to cover all areas and all needs (spawning aggregations and juvenile aggregations) and then it was decided to concentrate all efforts and resources only on bluefin tuna spawning aggregations.

### 4.1 Aerial survey design

The preliminary work was devoted to identifying the most relevant areas and this was carried out at the ICCAT Secretariat using the 2008 and 2009 VMS data from purse seine vessels. It was agreed to concentrate efforts only on areas where the purse seine fishing activity was more intense in these last two years and 6 sub-areas were identified.

The study for the aerial survey was awarded to a well-known specialist, who provided a detailed design, which is statistically sound and able to balance the available funds with the flight hours required. After two revisions, the design was provided on 1 May 2010 and the ICCAT Secretariat provided the file to submit the survey data.

### 4.2 Aerial survey on spawning aggregations

The aerial survey on spawning aggregations was carried out by three companies, selected from among seven tenders and the contracts were discussed and agreed from 11 to 13 May 2010. All tenders were able to obtain flight permits from Spain, Italy, Malta, Cyprus and Turkey in due time, but it was not possible to obtain flight permits from Libya and Tunisia, while the permit from Egypt was changed and withdrawn when the aircraft entered Egyptian airspace. All these problems imposed a revision of the contracts and, at the same time, a revision of the aerial sampling design. The aerial survey started on May 24 and ended on August 3.

Two sub-areas were cancelled and another was reduced, creating a serious problem for the survey in general, because the biological information on bluefin tuna spawning and behaviour in these areas was almost nonexistent. In agreement with the Steering Committee, it was decided to define two additional sub-areas, where fishing activity on spawners was present in 2008 and 2009, providing in the emergency a new aerial survey design for those new sub-areas and amending one contract accordingly.

The monitoring of the sea surface temperatures and sea state and winds was carried out by the Coordinator and data were provided to the various teams in real time. The unfavourable weather conditions and the cold water temperatures in spring 2010 created additional operational problems for the aerial survey, prolonging the time required to fulfil the necessary flight time. A delay in bluefin tuna spawning activities was noticed in several sub-areas. Five aircraft and teams conducted the surveys in the various sub-areas. The aerial survey data have been provided on schedule by all teams and the individual reports are already available.

A contract was granted to a company on 6 August 2010 to analyse the aerial survey data. The report was provided in due time ( 27 September 2010) and the results are considered very useful for improving the aerial survey activities in the following years. This first year's aerial survey activity is considered essential and extremely useful to better plan and refine the next aerial surveys, including the necessary preliminary official contacts with all CPCs interested in the aerial survey activities, in order to inform the local Authorities and to obtain the flight permits on time.

## 5. Data mining and data recovery

The first preliminary activity was conducted at the ICCAT Secretariat. An analysis of the ICCAT database on bluefin tuna was carried out for the purpose of identifying the most relevant gaps in the data series which are potentially useful for the stock assessment. This gap analysis was provided by the GBYP to the SCRS scientists and national statistical correspondents to help them in detecting the missing data.

Three Calls for Tenders were issued on this item and five contracts were awarded on 30 July 2010 to various entities, public and private. The various proposed data sets, actually missing from the bluefin tuna database, concern about 180,000 specimens and a wide range of years and gears, and should improve knowledge on several fisheries in various areas. A common format for transmitting the data to the ICCAT Secretariat was provided to all the contractors, with the purpose to obtaining the data "ready to use" and in a format allowing their immediate incorporation in the bluefin tuna database. Many data sets have been already provided to the GBYP on due time. The final report must be submitted by 4 October 2010.

Sea surface temperature data sets will be acquired, to allow various type of analysis, either for VMS or aerial survey data.

## 6. Tagging design

This item is considered extremely relevant because it should provide a better estimate of natural mortality rates (M) by age or age-groups and/or total mortality (Z). It should provide also updated tagging reporting rates by major fisheries and areas, and it should improve the knowledge on habitat utilisation and movement patters of bluefin tuna in the various areas. It will provide the base to carry out the tagging activities in the following years, with important implications on the GBYP budget. This item was largely discussed, at first at the Secretariat level, and then with the Steering Committee, because of the various possible options of tagging techniques and their different possible uses for the assessment. At the end of the discussion, a Call for Tender was issued on 26 July 2010 and a single bid was received. The Steering Committee (4-5 September 2010, in agreement with the ICCAT Secretariat and the GBYP Coordinator) asked the tender to modify the proposal, in order to obtain a tagging design limited to the eastern Atlantic and Mediterranean, for conventional tags and PITs (and electronic tagging in Phase 3), and to verify the practical tagging possibilities with tuna trap owners and purse seine fishermen, and including a manual for tagging. The official request to modify the offer, also taking into account the revised and reduced budget adopted by the Steering Committee, was delivered on 14 September 2010 and the revised offer arrived on 24 September 2010 and is now under examination.

## 7. Definition of GBYP publication policy, editorial and data rules

The need to have a clear and defined publication policy, along with editorial and data use rules, was one the first issues undertaken within the GBYP coordination. Discussion was carried out at the Secretariat level, taking into account the ICCAT rules in this sector and the SCRS statements, and the final document was officially adopted on 15 March 2010.

## 8. GBYP web page

It has been agreed that the ICCAT Secretariat would add a GBYP page to the official ICCAT web page, for the purpose of providing full and transparent information about all the activities carried out by the GBYP. This page will be updated regularly.

## 9. Following activities

The next phases of the Atlantic-Wide Research Programme for Bluefin Tuna will only include activities able to provide fishery-independent data and indices within the time-frame of the overall programme and in agreement with the GBYP general plan adopted by the SCRS and the Commission. Due to the limited budget available for Phase 2 (2010-2011) some activities already included in the original general planning have been temporarily excluded (i.e., egg and larval survey, intercalibration of aerial surveys), others have been delayed (i.e., electronic tagging), while others (i.e., conventional and PITs tagging) have been considerably reduced. The Steering Committee agreed to keep only the activities already initiated or absolutely essential for the programme, but confirmed the need to follow the original list and volume of activities whenever appropriate funds are available. For this reason, GBYP Phase 2 is considered a contingency minimal programme, while a similar strategy is temporarely planned for Phase 3.

GBYP Phase 2 (under the reduced minimum budget perspective) will include the following activities:

1) Coordination, reinforcing the coordination team with two additional staff (1 G2.1 and 1 P 2 ), due to the workload and with contracts for the external members of the Steering Committee.
2) Data mining, data retrieval and data elaboration, including data collection on juveniles from small-scale and recreational fisheries, elaboration of VMS, environmental and aerial survey data, and a symposium on tuna trap data issues.
3) Aerial surveys, including a workshop to refine the activity, the revision of the aerial survey design, a training course for pilots, spotters and observers, and the $2^{\text {nd }}$ year survey on spawning aggregations.
4) Tagging, including conventional and PITs tagging and activities to improve tag reporting and tag recovery, with related rewards.
5) Biological sampling, including hard parts sampling for ageing and micro-constituent analysis, genetic sampling and related analysis.
6) Modelling, only including a workshop on modelling approaches.

GBYP Phase 3 (still temporarily under the reduced minimum budget perspective) will include the following activities:

1) Coordination.
2) Data mining, data retrieval and data elaboration, including data collection on juveniles from small scale and recreational fisheries, elaboration of VMS, environmental and aerial survey data.
3) Aerial surveys, including the up-dating of the aerial survey design and the $3^{\text {nd }}$ year survey on spawning aggregations.
4) Tagging, including conventional and PITs tagging, a limited electronic tagging and activities to improve tag reporting and tag recovery, with related rewards.
5) Biological sampling, including hard parts sampling for ageing and micro-constituent analysis, genetic sampling and related analysis.
6) Modelling, including modelling trials.

The GBYP Phase 3 budget and activities will be revised by the Steering Committee and SCRS in the last part of Phase 2, according to the updated budget perspectives and the research needs.

The provisional calendar for the meetings is as follows:

- Symposium on Tuna Trap Fishery and Data Standardisation: May 2011 (in Italy, Morocco or Spain, 3 days);
- Training course for aerial survey staff: May 2011 (ICCAT Secretariat, 2 days)
- Modelling Workshop: July 2011 (ICCAT Secretariat, 5 days).

## ICCAT ENHANCED RESEARCH PROGRAM FOR BILLFISH

(Expenditures/Contributions 2010 \& Program Plan for 2011)

## Summary and Program objectives

The ICCAT Enhanced Research Program for Billfish, which began in 1987, continued in 2010. The Secretariat coordinates the transfer of funds and the distribution of tags, information, and data. The General Coordinator of the Program is Dr. David Die (USA); the East Atlantic coordinator was Mr. Paul Bannerman (Ghana), while the West Atlantic coordinator is Dr. Eric Prince (USA).

The original plan for the ICCAT Enhanced Research Program for Billfish (IERPB, SCRS 1986) included the following specific objectives: (1) to provide more detailed catch and effort statistics, particularly for size frequency data; (2) to initiate the ICCAT tagging program for billfish; and (3) to assist in collecting data for age and growth studies. During past Billfish Species Group meetings, the Billfish Species Group requested that the IERPBF expands its objectives to evaluate habitat use of adult billfish, study billfish spawning patterns and billfish population genetics. The Billfish Species Group believes that these studies are essential to improve billfish assessments. Efforts to meet these goals continued during 2010 and are highlighted below.

The program depends on financial contributions, including in-kind support, to reach its objectives. This support is especially critical because the largest portion of billfish catches is, in recent years, coming from countries that depend on the support of the program to collect fishery data and biological samples. In recent years most of the financial support came from ICCAT funds but in 2009 there was also a contribution from Chinese Taipei.

## 2010 Activities

The following is a summary of the activities of the Program; more details of activities conducted in the western Atlantic can be found in SCRS/2010/150 and in SCRS/2010/100. Five observer trips onboard Venezuelan longline vessels were completed by July 2010 and some more may be completed before the end of the year. Sampling of Venezuelan artisanal catches also continued in the central coast of Venezuela and more than 1700 trips were monitored. Biological sampling from both the pelagic longline and artisanal Venezuelan fisheries has provided more than 11,000 samples. These included more than 6000 sailfish, more than 1700 blue marlin and almost 1000 white marlin spines and gonads for age, growth and reproductive studies. This year this program recovered 45 tagged billfish before August 2010.

The IERPB continued to support Brazil in their collaboration with United States institutions for testing the performance of circle hooks on board commercial vessels, deploying pop-up satellite tags, tissue sampling for genetic analyses, and fin spine sampling for age and growth studies. With IERPB support, Uruguay continued to collect samples this year for age, growth and genetic analysis of billfish onboard longline vessels. Barbados provided the IERPB with data catch and effort on billfish recreational tournaments and has also reinitiated its billfish tagging program.

In West Africa the program continued to support a review of billfish statistics in Ghana, Senegal and Cote d'Ivoire. Improvements of catch records from these countries are reflected in the Task I tables for billfish, and were obvious during the marlin data preparatory meeting of 2010. Support of this program facilitated the estimation of relative abundance indices for Cote d'Ivoire, Ghana and Senegal during 2010, and studies of spawning of billfish in Cote d'Ivoire. The program also profited from the cooperation with Spanish scientists that collected biological samples of billfish on-board purse seiners.

Documents that were produced in 2010 with the benefit of direct support of the IERPB were SCI/2010/023, SCI/2010/024, SCI/2010/030, SCRS/2010/020, SCRS/2010/021, SCRS/2010/027, SCRS/2010/049, SCRS/2010/093 and SCRS/2010/100.

## 2011 Plan and activities

The highest priorities for 2011 are to support the improvement of data on the genetic identification of white marlin in the historical catches of white marlin and to continue improving the statistics of artisanal fisheries Atlantic-wide. Such priorities will require to continue:

- the support of the monitoring of the Uruguayan, Venezuelan and Brazilian longline fleet through onboard observers, reporting of conventional tags, and biological sampling.
- the support of biological sampling in western Africa.
- to support the processing of historical samples of white marlin spines for genetic studies.

All these activities depend on successful coordination sufficient financial resources and adequate in-kind support. Details of IERPB funded activities for 2011 are provided below. Some of these will complement general improvements in data collection made with the support of the ICCAT data improvement program.

## Shore-based sampling

Sampling of artisanal and small scale fisheries to support the estimation of catch and effort statistics will be focused on fleets contributing the largest parts of the catch and/or those having traditionally provided the higher quality data in the past, to ensure the preservation of an uninterrupted time series of catch and relative abundance indices.

## West Atlantic

Sampling at landing sites will be conducted for gillnet landings in central Venezuela.

## Eastern Atlantic

Monitoring and sample collection will be supported for the artisanal fisheries of Ghana, Côte d'Ivoire, and Senegal.

## At-sea sampling

## West Atlantic

Continued support will be provided to the sampling made onboard the Uruguayan, Venezuelan, and Brazilian vessels that have been supported in the past by IERPB

## Tagging

The program will need to continue to support conventional tagging and recapture reporting conducted by program partners.

## Biological studies

The biological sampling program for collecting and processing genetic samples from billfish, particularly white marlin and spearfish, will continue in 2011. This program will aim to determine the ocean-wide ratio of white marlin to roundscale spearfish, including how this ratio has changed through time. The later will be done by taking advantage of the spine collections (from Venezuela, Uruguay, Brazil, Spain, and the United States) collected in the past with the support of the IERPB.

Efforts to collect biological samples for reproduction, age and growth studies requires IERPB support to facilitate cooperation from fleets that are monitored with IERPB funds. The emphasis of biological sampling for age, growth, and reproductive studies will be directed at sailfish and longbill spearfish.

## Coordination

## Training and sample collection

Program coordinators need to travel to locations not directly accessible to promote IERPB and its data requirements. This includes travel to West African countries, as well as the Caribbean and South America by the general coordinator and the coordinator from the west. Strong coordination between activities of the IERPB and the ICCAT data improvement project will continue to be required.

## Program management

Management of the IERPB budget is assumed by the program coordinators, with the support of the Secretariat. Reporting to the SCRSC is responsibility of the coordinators. Countries that are allocated budget lines for program activities need to contact the respective program coordinators for approval of expenditures before the work is carried out. Invoices and brief reports on activities conducted need to be sent to ICCAT to obtain reimbursement of funds.

## 2010 Budget and Expenditures

This section presents a summary of the contributions and expenditures for the ICCAT Enhanced Research Program for Billfish during 2010. The 2010 budget recommended by the Billfish Working Group for IERPB was $€ 39,850.00$. The only contributions made to the IERPB during 2010 were an allocation of $€ 30,000.00$ from the regular ICCAT budget. Carryover funds remaining from previous years were $€ 4,978.80$ thus total funds available for 2010 were $€ 34,978.80$ (Table 1). As a consequence some planned activities of the program were not carried out. Expenditures to date in 2010 were $€ 16,281.00$ but an additional $€ 16,700.00$ are already committed to other activities that have either taken place in 2010 or will take place between October and December. The estimated balance of the program at the end of 2010 will be $€ 1,997.80 €$ (Table 2). These unspent funds correspond to savings in the travel from the coordinator for the East who used support from the ICCAT fund to fulfill his coordination travel duties.

In-kind contributions to the program continued to be made during 2010. INIA and the University of Oriente (Venezuela) have provided personnel and other resources as in-kind contributions to the at-sea sampling program, thereby reducing the amount of funds needed for this activity from the ICCAT billfish funds. Also, the western, eastern and overall program coordinators traveled to through each of the region of responsibility to oversee IERPB work. Travel expenditures for these trips were absorbed by the U.S. National Marine Fisheries Service, the University of Miami and, and by the ICCAT Data Fund that supported and as such, represented inkind contributions to IERPB for 2010. Ghana and Senegal provided in-kind contributions by supporting the time spent in the program by Mr. Bannerman and Mr. T. Diouf (Senegal) co-coordinators for the Eastern Atlantic.

## 2011 Budget and requested contributions

The summary of the 2011 proposed budget, totaling $€ 46,850.00$ is attached as Table 3. The Working Group requests that the Commission increases its contribution from $€ 30,600.00$ to $€ 45,600.00$ for 2011 to cover urgent needs of the IERPB program (see Table 4). The requested contribution from ICCAT is necessary to fully implement the IERPB 2011 program plan.

The consequence of the Program failing to obtain the requested budget will be to stop or reduce program activities for 2011 including: (1) important at-sea observer trips in Venezuela, Uruguay and Brazil; (2) coordination travel for eastern coordinators; (3) sampling of artisanal fleets in the western and eastern Atlantic (4) sampling and processing of genetic, age and growth samples; (6) promotion of conventional tagging activities, including distribution of tag recovery incentives.

## Conclusion

The IERPB has been credited for major improvements in the data supporting the last ICCAT billfish assessments. In preparation for the assessments of marlins the Program needs to continue to facilitate the collection of biological and fishery information. If the IERPB Program were to be terminated due to lack of funds, essential research and monitoring activities that are now supported by the Program will suffer and the Working Group will be in a difficult position to address the needs of the Commission, specially the upcoming assessment meetings for blue marlin and white marlin. Although considerable benefits will accrue from various outputs of the ICCAT data improvement program, the IERPB is the only program that exclusively focuses on billfish. By having this focus it is in the best position to ensure that the research and monitoring activities not covered by the ICCAT data improvement program are given some minimal resources. The IERPB is an important mechanism towards completing the goal of having the highest quality information to assess billfish stocks.

Table 1. Summary budget for 2010 for the Billfish Program.

| Source | Euros (€) |
| :--- | ---: |
| Balance at start of Fiscal Year 2010 | $4,978.80$ |
| Budget recommended by the Working Group | $39,850.00$ |
| Income (Allocation from ICCAT Regular Budget) | $30,000.00$ |
| Expenditures and obligations (for details see Table 2) | $-32,981.00$ |
| Estimated BALANCE | $\mathbf{1 , 9 9 7 . 8 0}$ |

| Source | Euros ( $€$ ) |
| :--- | ---: |
| Balance at start of Fiscal Year 2011 (estimated) | 1997.80 |
| Income (Requested from ICCAT Regular Budget) | $30,600.00$ |
| Other contributions) | $15,000.00$ |
| Expenditures (see Table 4) | $46,850.00$ |
| BALANCE | $\mathbf{7 4 7 . 8 0}$ |

Table 4. Detail of expenditures planned for 2011.

| Source | Amount $(€)$ |
| :--- | :---: |
| STATISTICS \& SAMPLING |  |
| West Atlantic shore-based sampling: |  |
| Venezuela | $5,000.00$ |
| West Atlantic at-sea sampling: |  |
| $\quad$ Venezuela | $6,000.00$ |
| Uruguay | $2,000.00$ |
| Brazil | $5,000.00$ |
| East Atlantic shore-based sampling: |  |
| $\quad$ Senegal | $3,000.00$ |
| Ghana | $3,000.00$ |
| Côte d'Ivoire | $3,000.00$ |
|  |  |
| Processing of Genetic samples | $17,000.00 *$ |
| Lottery rewards - tagging billfish | 500.00 |
| COORDINATION | $2,000.00$ |
| Coordination travel East Atlantic | 100.00 |
| Mailing \& miscellaneous | 250.00 |
| Bank charges |  |

GRAND TOTAL
46,850.00
Authorization of all these expenditures depends on sufficient funds being available by ICCAT and from other contributions.

* Number of samples processed will depend on the final budget of the program.

## REPORT OF THE SUB-COMMITTEE ON STATISTICS

(Madrid, Spain - September 27-28, 2010)

## 1. Opening, adoption of Agenda and meeting arrangements

The Sub-Committee on Statistics met at the ICCAT Secretariat (Madrid, Spain) on September 27-28, 2010. The meeting was chair by Mauricio Ortiz and Shannon Cass-Calay served as repportour. The revised Agenda proposed by the Chair was accepted and adopted by the Sub-Committee (Addendum 1 to Appendix 8).

## 2. Review of fisheries and biological data submitted during 2010

The Secretariat presented document SCI-008, a detailed description of the electronic data received by the Secretariat between December 1, 2009 and September 17, 2010 (hereafter referred to as the "Reporting Period"). During the reporting period, the official statistics received and processed by the Secretariat included about 647,000 records, the majority (about $80 \%$ of the total) reported using the standard ICCAT electronic forms. This percentage is similar to that in 2009 (after improvements from $60 \%$ in 2007 and $70 \%$ in 2008), indicating progress toward the goal of $100 \%$ electronic reporting. However, the Secretariat noted that submission of incomplete electronic forms continues, which complicates efforts to validate the data.

The Secretariat reiterated to the CPCs the Commission's requirement to use the standard electronic forms, which greatly decreases the Secretariat's workload, substantially reduces data manipulation errors and improves the ability to provide data in a timely fashion. The Sub-Committee reviewed document SCI-008 and made several recommendations which are described below.

### 2.1. Task I

The Secretariat noted that historical data regarding fleet characteristics are incomplete for some important fleets. In 2010, 28 CPCs reported complete data regarding fleet characteristics while 24 CPCs have not yet submitted complete data. The Secretariat also noted an improvement in the timely submission of Task I nominal catch data by the CPCs during the reporting period. A summary of compliance with Task I submission deadlines by CPCs was discussed. As of September 17, 2010, 15 CPCs had not yet reported Task I data. Additional CPCs failed to meet reporting deadlines, but did report Task I data following the deadline. The Sub-Committee noted that multiple data submission deadlines were announced for certain species in 2010 due to the newly scheduled "Data Preparatory" and "Assessment" workshops. This resulted in confusion regarding the interpretation of submission deadlines. To this end, the Sub-Committee recommended that Species Group Rapporteurs clearly communicate (in the annual working plans) data submission objectives, responsibilities and deadlines to the working group and to ICCAT. Lacking clearly defined deadlines, the Secretariat must use default deadlines that may deviate from the plan of the working group. The Sub-Committee also resolved that the 2010 Task I submission deadlines for BET, BUM and WHM be set to the default submission deadline (July 31, 2010) and that CPCs that reported data by that date be considered in compliance with the submission deadlines.

The Sub-Committee also noted that the interpretation of document SCI-008 tables regarding Task I data submission is hampered by the inability to discriminate CPCs that do not report because they do not land a given species, and CPCs that fail to report non-zero landings. To that end, the Sub-Committee recommended that CPCs report cero catch for those ICCAT species not caught in the Task I forms.

The Secretariat also reported that some Task I data cannot be directly allocated to a given species stock unit because a concise geographic delimitation of Task I area is lacking. The Secretariat proposed, and the SubCommittee approved that the following change be made to the Task I submission form: (1) Beginning in 2011, the species "sampling area" variable, available in form ST02-T1NC, will be the mandatory aggregated geographical level in Task I submission form. (2) However, for the next two years, this variable AND the existing variable (Task I Area) will be retained. (3) After that time the existing variable (Task I Area) will be deleted from the Task I data submission form since it is not sufficient (or is not always used appropriately) to consistently discriminate species stock units and may cause confusion. The two year overlap of variables will allow CPCs and statistical correspondents to make their modifications in the estimations of total Task I annual reports.

### 2.2. Task II

The Secretariat reported that during the reporting period, Task II catch and effort data was received from 29 CPCs while 21 CPCs did not report Task II data. In general, data quality (temporal and spatial resolution) has improved recently. However, the Secretariat emphasized that some deficiencies and problems persist, including: missing or incomplete information, non-standard effort units, and double counting of fishing effort, particularly in mixed-species fisheries. The Secretariat recommended that SCRS scientists collaborate with their statistical correspondents to address these problems. The Secretariat reiterated that all CPCs must submit Task II catcheffort statistics for all species caught (targeted as well as non targeted fish species), and that data should be reported by month and by $5 x 5$ square degree (for LL) or 1 x 1 square (all other gears). The Sub-Committee discussed complications in reporting by-catch species, and concluded that both estimation and identification of by-catch species need to be validated. The Sub-Committee recommends that the Ecosystems WORKING GROUP and the Secretariat work together to develop a by-catch reporting form to be added to the ICCAT reporting e-forms.

The Secretariat also reported that Task II size frequency data was received from 23 CPCs during the reporting period, while 27 CPCs did not report. Compared to previous years, some improvement was noted in on-time data reporting and in the amount, and spatial/temporal resolution of size-frequency information provided. The Secretariat noted that some CPCs have informed ICCAT that they do not collect and/or possess size frequency information. The Sub-Committee noted that as in Task I, Task II data submission deadlines were not always clearly defined in 2010 due to multiple workshops for assessed species. The recommendations pertaining to Task I submission deadlines also apply to Task II.

### 2.3. Tagging

The Secretariat informed the Sub-Committee regarding data submissions from electronic and conventional tagging programs in 2009 and 2010. In 2009, information from 37 electronic tags were added to the database (EU-Spain: 5 pop-up tags, Japan: 1 pop-up tag, United States: 31 pop-up and archival tags). During 2010, the Secretariat received information from 225 additional electronic tags (Canada: 95, EU-Spain: 11, EU-France: 26 and USA: 93). This information included internal archival tags as well external archival pop-up tags released on bluefin and swordfish.

The Secretariat also reported that an updated electronic tag form is now available, which addresses the recommendations made by the bluefin tuna Working Group during the 2010 data preparatory meeting. The Secretariat reported that in 2010 USA submitted a tagging database for all years and species. It was noted, however that in 2009 the Secretariat and US scientist had collaborated to standardized the formats and protocols for tagging data submission. Therefore, the Sub-Committee recommended that scientist from US submit only updates and new tagging information to the Secretariat.

## 3. Updated report on the ICCAT relational database system

The Secretariat provided to the Sub-Committee a detailed description of the ICCAT database information system (SCI-008). The Secretariat emphasized that since 2009, the amount of compliance related data input and database management tasks have significantly increased, mainly in response to Commission Resolutions and Recommendations regarding bluefin tuna. To maintain real-time updates of compliance related information the Secretariat strongly recommends that the data transmission process, electronic data requirements and human resources at the Secretariat be reevaluated as soon as feasible. The Sub-Committee recommended that an external panel review in particular the Secretariat's task and responsibilities for both statistical and compliance related duties and evaluate the available human resources requirements. The Sub-Committee also endorses the Secretariat's proposal for making compliance related data submissions in electronic forms, rather than typing hard copies or paper images.

The Secretariat also reported that in 2010, the migration to the MS-SQL 2008 server was initiated. The Secretariat has made progress in drafting documentation for the relational database. Also, during 2009 and 2010 the Secretariat produced a series of R-scripts to produce preliminary data analyses and diagnostics for various models and input control files.

## 4. National and international statistical activities

In 2010, the CWP held its 23rd session. Unfortunately, the ICCAT Secretariat was not able to attend this meeting. Regarding the ad hoc working group on aquaculture, ICCAT responded to the request made to the RFMOs by the Secretariat of the CWP to provide information on activities related to aquaculture. Also, in collaboration with the FIRMS Secretariat, the ICCAT Secretariat also developed fact sheets for several shark stocks assessed by the SCRS. The Sub-Committee requested that the Secretariat provides to the CWP the name of a contact person at the Secretariat that replaces the role being done by Papa Kebe until last year.

### 4.1. National data collection systems and improvements

No major improvements were been made to the Task I and Task II databases. The Secretariat has continued to improve the detail level in CATDIS. For some species, additional gears were reclassified and removed from the aggregated gear type "others". A full revision of CATDIS was made available in May 2010 for the nine major ICCAT species with the objective to include 2008 statistics as well as specific revisions that were made to Task I since the prior version. The Secretariat also discussed plans to make important improvements to the CATDIS in 2011 including: (1) adopting a month as the base time strata instead of trimester when possible, and (2) ongoing reclassification and removal of unique gear codes from the aggregated gear type "other". The Secretariat described some improvements to the EFFDIS database in 2009, but noted that that database was not updated during 2010. The conventional tagging database was revised and updated in 2009. During 2010 cross-validation and quality control was carried out with the collaboration from scientists from EU-Spain, EU-France, Canada and United States. The Secretariat requested, and the Sub-Committee affirmed, that national scientists should submit only modifications and updates to conventional tagging data provided to ICCAT in previous years.

In collaboration with United States national scientists, the Secretariat updated and simplified (while maintaining the functionality) programs and algorithms for the age slicing of the Catch-at-Size data (AgeIT Program). The updated software, coded in R, provides more detailed information in relation to partial catch at age by fleets or gears to the working groups and is significantly easier to implement and revise as necessary. It was validated and applied during the 2010 bluefin tuna assessment meeting, and was commended by the Working Group as a very substantial improvement.

## 5. Report on data improvement activities

### 5.1. ICCAT-Japan Data and Management Improvement Project (JDMIP)

In order to improve the collection of data and strengthen the scientific capacity of some developing CPCs, the Japanese Government created the Japan Data and Management Improvement Project (JDMIP). This project is described in detail in document SCI-009 which will be presented to the SCRS during the plenary session.

### 5.2. Data Funds from [Res. 03-21]

One objective of the ICCAT Commission, Resolution 03-21, was that CPCs with sufficient resources should create special funds to provide training in data collection and to support scientific participation by scientists from CPCs with fewer resources. In addition to the JDIP (discussed above), the United States, European Union and the Commission Chairman made funds available for that same objective. During 2010, various funds were used to finance the participation of 26 scientists at meetings of the SCRS. In addition, 2 scientists were funded to participate at the joint ICES-ICCAT training course on Management Strategy Evaluation. The Secretariat noted that the application documentation for this program, including deadlines for transmittal of requests is available on the ICCAT web site. Nevertheless, the Secretariat receives the majority of requests after the deadline which greatly complicates the work of the Secretariat and unnecessarily increases travel expenses. Thus, the Secretariat has developed, and recommended to the Sub-Committee a protocol to request these funds (SCI-008 Appendix 1).

The Sub-Committee agreed that these funds are particularly useful to provide training opportunities, and have resulted in a notable increase in the number and quality of scientific publications from participating CPCs. The Sub-Committee approved the protocol prepared by the Secretariat and recommended that at a minimum, twoweek lead times be obligatory.

### 5.3. Data improvement and recovery activities

The Secretariat described improvements made to ICCAT statistical databases, including incorporation of the Task I disaggregation of SAI into SAI and SPF for relevant fleets as estimated during the 2009 Sailfish Stock assessment session, re-estimation of Ghanaian fisheries statistics, revisions to historical Task I (SCI-008; Table 6) and Task II (SCI-008; Table 7-8) data series, and the recovery of historic bluefin data under the GBYP Research Program. A detailed description of these activities can be found in Section 2 of document SCI-008. The Secretariat noted that many revisions have not been incorporated into the final statistics because they are pending approval. In general this occurs when revisions are submitted without an accompanying justification. The SubCommittee reiterated its previous recommendation that revisions not be incorporated without the approval of the appropriate species Working Group.

The Sub-Committee requested clarification of the status of the re-estimation of Ghanaian statistics, and the response of Ghana to ICCAT Recommendation [09-01], "Ghana’s Action Plan to Strengthen the Collection of Statistical Data and Control Measures to Ensure Full Implementation of Conservation and Management Measures". The Secretariat and the Ghanaian National scientist explained that the re-estimation has been submitted and incorporated. Also, the Secretariat brought to the attention of the Sub-Committee the ICCAT circular \#908/10, Ghana’s response to Rec. 09-01. The Sub-Committee acknowledged the prompt and capable assistance provided by the national scientists and the Commissioner of Ghana with regard to these matters. The Sub-Committee recommends that the tropical tunas Working Group continue their work on the review and improvement for catch and effort statistics from the Gulf of Guinea in particular in coordination with scientist and research programs involved in this mixed fisheries.

### 5.4. BFT-E VMS data

Recommendation [08-05] states that VMS information submitted to the Secretariat can be made available to the SCRS upon request. However, at present, ICCAT has not yet adopted a policy on the treatment and distribution of data that can be deemed to be confidential. Therefore, the Secretariat is unable to provide a database for scientists, besides overall annual summaries. The Sub-Committee reiterated its desire to use VMS information to inform scientific analyses. To emphasize the importance of the confidentiality agreement, the Sub-Committee agreed that the confidentiality agreement be re-submitted to the Commission in 2010.

### 5.5. BFT-E observer data

The Sub-Committee reviewed and discussed the document prepared by the Marine Resources Assessment Group (MRAG) regarding the BFT-E regional observer program (ROP) (SCI-060). The Sub-Committee disagreed with some language contained in that document, particularly the explanation of the objective of the ROP which primary emphasized compliance monitoring. The Sub-Committee strongly emphasized the "Equal Importance" of collecting scientific information to support SCRS analytical objectives. The Sub-Committee also felt that the primacy of the compliance monitoring activities, as defined by MRAG, was contradicted by SCRS the recommendation presented to and approved by the ICCAT Commission [Rec. 08-05]. Specifically, that the ROP carry out such scientific work as required by the Commission based on the directions from the SCRS, including but not limited to: (1) the collection of data regarding fishing activity (e.g. temporal and spatial distribution effort) for management strategy evaluations, catch-per-unit effort analyses and capacity analyses), and (2) the collection information regarding the disposition of BFT discarded or released to improve estimates of total removals.

### 5.6. BFT-E weekly catch reports

Under Recommendation [08-05], weekly catch reports are sent to the Secretariat. The information obtained through September 17, 2010 was presented to the Sub-Committee (SCI-008; Table 10).

### 5.7. Transshipment observer data

Recommendation [06-11] established a program to monitor at-sea transshipments by large scale longliners. The Secretariat summarized the amounts transshipped in document SCI-008 (Table 13a) and noted that there are many product types for which the Secretariat has no conversion factors (Table 13b) making impossible the conversion to round-weight. The Secretariat recommended, and the Sub-Committee concurred that the SCRS develop and adopt conversion factors to facilitate use of this data.

## 6. Review of publications and data dissemination

### 6.1. Review of the results of the ICCAT-Aquatic Living Resources publication agreement

The Secretariat reported that the second issue of the scientific journal Aquatic Living Resources (ALR) was published in 2010, including a thematic section on tuna and tuna-like species. Six documents presented to the SCRS in 2009, were included in this section. In addition, there are currently eleven documents accepted for publication, or in the process of being reviewed. The documents that are finally accepted will be published in the corresponding thematic section of the journal.

### 6.2. Development of small tunas and sharks identification species sheets

The Secretariat updated the fact sheets for several species assessed by the SCRS in 2009, including: north Atlantic albacore, Atlantic swordfish (north and south). Also, in collaboration with the FIRMS Secretariat, the ICCAT Secretariat developed fact sheets for several shark stocks assessed by the SCRS.

## 7. Review of progress made for a revised ICCAT Manual

The Secretariat summarized the progress made in 2010 to complete the ICCAT Manual, including the following. Japanese national scientists have submitted a description of the "Japanese" longline gear used to catch has tunas and tuna-like species. The Secretariat has also contacted other experts on surface longline gear, as well as experts on southwest Atlantic fisheries. The Secretariat also noted the value of including a description of the longline gear used by artisanal fisheries if it becomes available. In addition, Chapter 2 of the ICCAT Manual was also published in 2010 in the three official ICCAT languages. Scientists from Spain and Canada continue to develop sections describing the harpoon and trolling gears.

## 8. Consideration of recommendations from 2010 inter-sessional meetings

The Sub-Committee on Statistics reviewed the 2010 Working Group recommendations pertaining to statistics, data collection and reporting. There were many important recommendations, some of which are addressed specifically below. The Sub-Committee recommended that particularly useful and/or complicated recommendations be brought to the attention of the Species Group rapporteurs at the SCRS officers meeting before the 2010 ICCAT Plenary Session. Pending approval of the SCRS officers, the Sub-Committee has also expressed approval for these measures.

### 8.1. Working Group on Stock Assessment and Methods

The Working Group on Stock Assessment and Methods made several important recommendations including the following:

### 8.1.1. Standardized Executive Summary Table Format

The Methods Working Group developed and proposed a standardized format for the executive summary table (Appendix 1, Working Group Methods and Assessment report). This table was presented to the Sub-Committee. The Sub-Committee agreed that was of potential value, and recommended that this table be presented to the Species Group rapporteurs for approval at the SCRS officers meeting before the 2010 ICCAT Plenary Session.

### 8.1.2. Model analyses, assumptions and duplicability

The Methods Working Group noted the lack of uniformity in reporting model specification, assumptions and data inputs across species and years, and the resulting difficulty in reproducing model results. They urged the development of standardized formats for the detailed report. The Sub-Committee agreed that was of potential value, and recommended that this issue be presented to the Species Group chairs for comment at the SCRS officers meeting before the 2010 ICCAT Plenary Session. Pending approval of the Species Group rapporteurs, the Sub-Committee recommends the development of standardized formats for the "Detailed Reports".

### 8.1.3. Kobe-II matrix construction

The Secretariat also reminded the Sub-Committee that the Methods Working Group recommended, and the Commission has required the construction of Kobe II strategy matrices (K2SM) for all ICCAT stock assessments. The construction and usage of K2SM is described in the 2010 Report of the Working Group on Stock Assessment and Methods. The Sub-Committee recommended that Species Group rapporteurs be made aware of this requirement at the comment at the SCRS officers meeting before the 2010 ICCAT Plenary Session.

### 8.2. Ecosystems (ECO) Sub-Committee

The Sub-Committee on Ecosystems also requested that the Secretariat develop the necessary mechanisms for CPCs to annually report their observer data (e.g., electronic forms, species codes, etc.) To that end, 27 new species codes were proposed (in collaboration with FAO). These were presented to the Sub-Committee on statistics in document SCI-058. A subgroup of the Sub-Committee met to discuss the elimination of duplicate scientific names for some species. They retained the most commonly used name and presented a revised table of codes to the Sub-Committee (SCI-058A) who approved the revised table for use.

The Sub-Committee on Statistics also discussed problems associated with the reporting of by-catch. First, there are no specific forms or submission formats. Second, by-catch is difficult to estimate because it is difficult to identify CPCs that did not observe a by-catch species (e.g. zero catch) from CPCs that do not report. Also, it is difficult to estimate annual by-catch because many species are rarely encountered, and therefore accurate annual estimates cannot be computed using typical estimation techniques. The Secretariat agreed that there is no standardized format, but described the by-catch data recently submitted by a CP (United States). The observed by-catch data of seabirds was submitted in numbers by species, month/quarter, and disposition (e.g. discarded dead or released alive). Some CPCs (Canada, Brazil, Uruguay) agreed that it might be possible to submit data soon in a similar fashion.

### 8.3. Bluefin Tuna Working Group

The bluefin tuna Working Group recommended that the Sub-Committee on Statistics should revise and adopt the new form for electronic tagging data at its meeting in September 2010 (SCI-031). The Secretariat presented the new form that is available in the ICCAT web page and it was approved.

### 8.4. Additional recommendations proposed by the Secretariat

### 8.4.1. $\quad R$ training workshop

The Sub-Committee strongly supported the Secretariat proposal to conduct a series of workshops, beginning in 2011 to introduce, provide training, validate and distribute these R-scripts to SCRS scientists in order to optimize and standardize common pre-analysis data processing tasks within each Species Group. The Sub-Committee approved of this important activity, and recommended that test datasets be developed to allow validation of RScripts and other processes which have been developed by National Scientists. A member of the Sub-Committee also reported that similar efforts have taken place another fisheries management group (ICES). This effort, the "COST Project", proposes the use of standardized data set exchange formats and emphasizes the development of R-scripts for common analyses. A report of this project is available (Jansen et al., 2009 - ICES Cooperative Research Report 296), and users may obtain R-scripts by contacting the user group.

## 9. SCRS proposal for collecting Recreational and Sport fisheries data on ICCAT species

A subgroup of the Sub-Committee (EU, Canada, Japan, Brazil, Mexico, United States) met to develop a proposal to facilitate the reporting of Sport and Recreational Fishing Statistics. The subgroup presented their conclusions to the Sub-Committee, and recommended the following data be collected by CPCs to facilitate the reporting of Recreational and Sportfishing data:

- Catch by species
- Length/Weight of catch
- Discards by species
- Length/Weight of discards
- Disposition of discards (e.g. dead, alive, etc.)
- Location and time of fishing trip
- Estimates of release mortality

The subgroup also made the following recommendations regarding data collection programs:

- Each CPC should identify the "universe" of recreational fishing participants.
- Each CPC should sample that universe with appropriate coverage to allow estimation of total removals (e.g. random stratified scientific sampling).
- Each CPC should identify release mortality to allow estimation of total removals (landed + dead discards + release alive then died due to interaction with fishery).

The Sub-Committee generally agreed with the recommendations of the sub-group and concluded that these recommendations should be submitted to the Secretariat as an official response to (SCRS report Response to Commission reference), and evaluated by the SCRS during the 2010 Plenary Session.

## 10. Evaluation of data deficiencies pursuant to [Rec. 05-09]

### 10.1. Proposals for data recovery plans and improvements on data collections systems

The Sub-Committee requested clarification of the status of the re-estimation of Ghanaian statistics, and the response of Ghana to ICCAT Recommendation [09-01], "Ghana’s Action Plan to Strengthen the Collection of Statistical Data and Control Measures to Ensure Full Implementation of Conservation and Management Measures". The Secretariat and the Ghanaian national scientist explained that the re-estimation has been submitted and incorporated. Also, the Secretariat brought to the attention of the Sub-Committee the ICCAT Circular \#908/10, Ghana’s response to Rec. 09-01. The Sub-Committee acknowledged the prompt and capable assistance provided by the national scientists and the Commissioner of Ghana with regard to these matters.

## 11. Review of existing data submission formats and procedures

### 11.1. Improvements to the ICCAT coding system

See Section 8.2, paragraph 1.

### 11.2. Rules applied to historical data revisions

No modifications. The Sub-Committee reiterates that historical revisions must be submitted with supporting documentation explaining the reason for submission. These materials will be forwarded to the Species Groups for approval. No changes will be made to ICCAT statistics until approval by the Species Groups. The Secretariat noted that many revisions have been submitted without the supporting documentation, and therefore cannot be approved by the Species Groups. Thus, many revisions submitted years ago are still pending. The SubCommittee recommends that CPCs who have submitted revised series promptly provide supporting documentation if it is lacking.

### 11.3. Rules used to determine deadlines for submitting statistics

The Sub-Committee reiterates that Species Group rapporteurs must declare clear deadlines for data submission, and communicate those deadlines to the Working Group and the ICCAT Secretariat in the annual working plans presented to the SCRS. Rapporteurs should avoid vague terms and multiple poorly-specified reporting deadlines for workshops occurring in the same calendar year (e.g. data prep and assessment). If vague deadline are proposed, the Secretariat must employ default deadlines that may cause unforeseen complications.

### 11.4 Review of existing rules and procedures on data handling and dissemination

The Sub-Committee reiterates the importance of adopting the Data Confidentially Policy for the ICCAT Secretariat, and reminds the Commission that a proposal was approved and presented by the SCRS in 2009. The Sub-Committee also resolved that the Data Confidentially Policy will be resubmitted to the Commission at the 2010 ICCAT Commission Meeting.

## 12. Future plans and recommendations

The following is a summary of the different recommendations mentioned and adopted by the Sub-Committee during the meeting:

1. The Sub-Committee reiterates the importance of adopting the Data Confidentiality Policy for the ICCAT Secretariat, and reminds the Commission that a proposal was approved and presented by the SCRS in 2009. The Sub-Committee also resolved that the Data Confidentiality Policy will be resubmitted to the Commission at the 2010 ICCAT Commission meeting.
2. The Sub-Committee recommended that an external panel review in particular the Secretariat's tasks and responsibilities for both statistical and compliance related duties and evaluate the available human resources requirements. The Sub-Committee also endorses the Secretariat's proposal for making compliance related data submissions in electronic forms, rather than typing hard copies or paper images.
3. The Sub-Committee strongly supported the Secretariat's proposal to conduct a series of workshops, beginning in 2011 to introduce, provide training, validate and distribute these R-scripts to SCRS scientists in order to optimize and standardize common pre-analysis data processing tasks within each species group. The Sub-Committee approved of this important activity, and recommended that test datasets be developed to allow validation of R-Scripts and other processes which have been developed by National scientists and the Secretariat.
4. The Sub-Committee recommended that Species Group rapporteurs clearly indicate in their annual Work Plan the data required to be submitted and the deadline for the submission of such data. For inter-sessional meetings taking place before July 31, the deadline is two weeks prior to the start of the meeting. For intersessional meetings taking place after July 31, the data submission deadline is the default deadline of July 31, 2010.
5. The Sub-Committee reviewed the Secretariat's proposal for requesting "sampling area" as mandatory geographical classification for Task I form reports. The Committee recommended that each CPC report Task I by species stock units (or sampling area), rather than by species and Task I area as is currently done. The Secretariat should modify the electronic forms currently used for Task I data to accommodate this Recommendation.
6. The Sub-Committee recommended that CPCs report zero catch for those ICCAT species not caught in the Task I forms.
7. The Sub-Committee approved the protocol prepared by the Secretariat regarding travel funding for scientific meeting participation and recommended that at a minimum, two-week lead times be obligatory.
8. The Sub-Committee recommends that the tropical tunas Working Group continue their work on the review and improvement for catch and effort statistics from the Gulf of Guinea in particular in coordination with scientist and research programs involved in this mixed fisheries.
9. The Sub-Committee reiterated its desire to use VMS information to inform scientific analyses. To emphasize the importance of the confidentiality agreement, the Sub-Committee agreed that the confidentiality agreement be re-submitted to the Commission in 2010.
10. The Secretariat recommended, and the Sub-Committee concurred that the SCRS develop and adopt conversion factors to facilitate use of transshipment and trade data.
11. The Sub-Committee recommends that CPCs who have submitted revised series, historical reviews promptly provide supporting documentation if it is lacking.
12. The Sub-Committee recommended that scientist from United States submit only updates and new tagging information to the Secretariat

## 13. Other matters

No other matters were discussed.

## 14. Adoption of the report and closure

The meeting was adjourned and the report adopted at the SCRS plenary. The Chair thanked the participants and noted that for next year it will be a new chair for the Sub-Committee of Statistics and scientist interested should submit their nomination to the SCRS Chair.

## Agenda

1. Opening, adoption of Agenda and meeting arrangements
2. Review of fisheries and biological data (new and historical revisions) submitted during 2010
2.1 Task I (nominal catches and fleet characteristics)
2.2 Task II (catch \& effort and size samples)
2.3 Tagging
2.4 Trade information (BFT Catch Documentation scheme; SWO/BET Statistical Documents)
2.5 Other relevant statistics
3. Updated report on the ICCAT relational database system
4. National and international statistical activities
4.1 International and inter-agency coordination and planning (FAO, CWP, FIRMS)
4.2 National data collection systems and improvements
5. Report on data improvement activities
5.1 ICCAT-Japan Data and Management Improvement Project
5.2 Data Funds from [Res. 03-21]
5.3 Data recovery activities
5.4 BFT-E VMS data
5.5 BFT-E observer data
5.6 BFT-E weekly catch reports
5.7 Transhipment observer data
6. Review of publications and data dissemination
6.1 Review of the results of the ICCAT-Aquatic Living Resources publication agreement
6.2 Development of small tunas and sharks identification species sheets
7. Review of progress made for a revised ICCAT Manual
8. Consideration of recommendations from 2010 inter-sessional meetings
9. Evaluation of data deficiencies pursuant to [Rec. 05-09]
9.1 SCRS proposal for collecting Recreational and Sport fisheries data on ICCAT species
10. Review of existing data submission formats and procedures
10.1 Formats and e-FORMS improvement (to account for current fishery practices)
10.2 Improvements to the ICCAT coding system
10.3 Defining standardized methodology for collection of recreational and sport fisheries data for ICCAT species.
10.4 Other related matters
11. Review of existing rules and procedures on data handling and dissemination
11.1 Public domain information
11.2 Non-public domain information
12. Future plans and recommendations
13. Other matters
14. Adoption of the report and closure.

## REPORT OF THE SUB-COMMITTEE ON ECOSYSTEMS

(Madrid, Spain - September 29, 2010)
The Sub-Committee on Ecosystems met at the Secretariat on September 29, 2010. The meeting was chaired by Dr. Haritz Arrizabalaga (EU-Spain). The Chair opened the meeting and welcomed the participants. The agenda was revised and adopted (Addendum 1 to Appendix 9).

## 1. Review of new scientific information

Eight documents were presented under this agenda item. Document SCRS/2010/094 provided new information about the food habits of marlin, in a Bayesian context. The group encouraged this type of work since they provide important information that may allow food web modeling in the future.

SCRS/2010/127 documented differences in the size of loggerhead turtle caught by traditional drifting surface longliners targeting swordfish, and drifting surface longline targeting albacore, with respect to other four types of longlines. The drifting surface longline targeting albacore caught the smallest turtles. The group discussed the fact that the differences in the size of sea turtles caught between gears could be due to factors such as the size of the hooks and type of the bait. Participants added that squid bait usually provokes higher by-catch of turtles because it remains longer in the hook than other types of bait such as fish.

Document SCRS/2010/128 characterized the marine mammal by-catch of the Spanish Mediterranean pelagic longline fishery during the last decade. By-catch of these fisheries included several marine mammal species. Differences in catch per unit effort (CPUE, number of marine mammals per 1000 hooks) for each longline gear type are reported in this study. A total of 5,398.297 hooks were monitored, which yielded 56 marine mammals belonging to 4 different species. The average CPUE for the studied period was 0.011 marine mammals per 1000 hooks. Risso's dolphin (Grampus griseus) was the species most commonly caught. The longfinned pilot whale (Globicephala melas) was only present in the longline fishery targeting bluefin tuna (CPUE $=0.0038$ mammals per 1000 hooks) and traditional longline targeting swordfish (CPUE $=0.0006$ marine mammals per 1000 hooks. In general, low by-catch and high survival rates were observed.

Document SCRS/2010/140 presented the statistics of tuna surface fishery's by-catch landed in Abidjan, Côte d'Ivoire, for the period 1982-2009. Besides some tropical tunas, the statistics also included several other finfish species that are of interest to the Sub-Committee, such as wahoo, dorado, barracuda and triggerfish. The best way to incorporate this information into the ICCAT database is being discussed by the Subcommittee on Statistics.

Document SCRS/2010/142 analyzed the effect of different levels of sampling coverage on by-catch estimates in the tropical tuna purse seine fishery. The analysis was based on resampling from a FAD by-catch dataset from the IATTC, with focus on four species. In general, the conclusions were comparable to those obtained during the Sub-Committee's inter-sessional meeting. In general, the largest gains in precision occurred when coverage increased to $5-10 \%$ (although estimates might remain highly imprecise for less frequent species). Document SCRS/2010/141 followed with a characterization of by-catch and discards in the Atlantic tropical tuna purse seine fishery for the years 2008 and 2009, which were comparable to those presented in the past.

Document SCRS/2010/151 presented preliminary results of the effect of hook type and bait on the catches of marine turtles by the pelagic long-line fishery in the equatorial area. A total of 164 long-line sets were carried out and analyzed. Three different hook types were used in each long-line set: traditional J hook (EC-9/0-R); G a non-offset circle hook (H17/0-M-S) and GT a $10^{\circ}$ offset circle hook (H17/0-M-R). The hooks were baited with mackerel (Scomber spp) and squid (Illex spp.), but only on type of bait was used in each set. Overall, a total of 219,801 hooks ( 73,275 J type; 73,272 GT type and 73,274 G type) were set. Overall, the use of the circle hooks reduced the mean CPUE by $50 \%$ to $70 \%$, with GT off-set style hooks showing the lowest catch of sea turtles. Hooks baited with mackerel showed lower catches than when squid is used as bait. Hooking location was species specific and not depending on the hook style. Leatherback were mostly entangled or hooked in the flippers, while the remaining species generally swallowed the hook. The overall mortality was lowest for the G style hook (12\%) and highest for the GT off-set style (33\%).

Document SCRS/2010/152 presented the International Seafood Sustainability Foundation initiatives to develop and test by-catch mitigation options for tropical purse seine fisheries. The research program aims to develop and test technical options to reduce by-catch resulting from industrial tuna fisheries. The initial emphasis will address ways to reduce the incidental mortality of bigeye tuna of undesirable size, oceanic sharks and marine turtles in tropical purse seine fisheries. The ISSF will implement field studies through the full charter of a dedicated purse seine vessel or vessels operating in the Pacific, Atlantic and Indian Oceans over a 24-month schedule, spread over three years. Overall project guidance will be provided by the ISSF Scientific Advisory Committee. A Purse Seine Research Vessel Steering Committee is developing the specific projects to be conducted while considering practical input from skippers and industry representatives gained from regional workshops convened by the ISSF. The first research cruise will be in the eastern Pacific Ocean early in 2011.

## 2. Other matters

The Group revised the inter-sessional meeting report (see Item 9.4) and the report of the joint tuna RFMO meeting on by-catch held in Brisbane, with special emphasis on future work of the subcommittee (see Item 13).

In addition, The United States announced that it is hosting the $1^{\text {st }}$ International Circle Hook Symposium in Research, Management, and Conservation. The symposium will be held in the City of Miami, FL, United States in May 4-6, 2011. The goal of the symposium is to produce an updated, science-based assessment of the management and conservation utility of circle hooks in commercial and recreational fisheries around the globe. It was indicated that the symposium is not a venue for advocating widespread use of circle hooks. Rather, its objective is to provide a forum for individuals, organizations and agencies to share relevant research results and perspectives and to subject their findings to peer-review through publication in an internationally-recognized scientific journal. Additional information about the symposium such as venue, lodging, deadlines, registration, etc. can be found in the symposium web site www.circlehooksymposium.org

## 3. Recommendations

The short term by-catch contractor compiled new information and generated new by-catch databases. However, these databases are not complete, and further information from other publications still needs to be compiled into these databases. These databases need to be kept operational to be useful and to help achieve the objectives and mandate of the SCRS. Moreover, it is essential to conduct quality controls on the new by-catch information submitted to the Secretariat and maintain the by-catch database. In addition, there is a need to work on the bycatch issues agreed by the Joint tuna RFMO Working Group on by-catch in Brisbane. Given the enhanced magnitude of by-catch related work that is anticipated, it is essential that the Commission funds a full-time Bycatch Coordinator position at the Secretariat.

Addendum 1 to Appendix 9

## Agenda

1. Review of new scientific information
2. Other matters
3. Recommendations
4. Work Plan for 2011

Mr. Driss Meski<br>Executive Secretary<br>International Commission for the Conservation of Atlantic Tunas<br>Dr. Gerald Scott<br>Chair, Standing Committee for Research and Statistics<br>International Commission for the Conservation of Atlantic Tunas

## Re: ISSF participating company data

Dear Mr. Meski and Dr. Scott,

As you are aware, ISSF participating companies are providing species / size data to RFMOs for their tuna purchases, as more fully described in the attached letter of October 6, 2009. This effort is designed to improve the species and size composition data used by RFMO scientific bodies, as more fully described in the ISSF Statement Resolution on Data Support that is also attached. Currently, the data from the ISSF Participating Companies is submitted directly to the RFMO contact that each RFMO has provided to us.

We have been contacted by a number of ICCAT SCRS member scientists seeking access to the data submitted by ISSF Participating Companies directly to the ICCAT contact that ICCAT has provided us. We are pleased that there is increasing interest in sharing the commitment of ISSF and its partners to improve the species and size composition data used by RFMO scientific bodies. It is certainly the intention of ISSF in providing these data sets for them to be used in a meaningful way by the RFMO scientific bodies.

In order for national scientists to conduct the analysis needed to improve the working of the scientific committee as part of the ICCAT process, I suggested that a mechanism (e.g., an MOU) that allows to access the data in a manner that maintains confidentiality, and within the frameworks that have already been established (i.e., ICCAT working group for tropical tunas, etc.) should be developed to support these research initiatives.

Yours sincerely,
(signed)
Susan S. Jackson
President

## To: ISSA Member Companies

## Re: Submission of information on unloading/landings and transshipments of tunas and tuna like species from participating companies of the International Seafood Sustainability Foundation (ISSF) to RFMO scientific bodies

As you are all aware, the International Seafood Sustainability Foundation (ISSF) is a global partnership among the tuna industry, science and WWF, the global conservation organization. The ISSF mission is to undertake science-based initiatives with all stakeholders to facilitate the long-term conservation and sustainable use of target fish stocks and to maintain the health of the marine ecosystem.

ISSF's first principle of governance is to cooperate closely with four major regional fishery management organizations (RFMOs) and their scientists. The second principle of governance is to follow and adopt sound scientific recommendations for sustainable management of targeted fish stocks. However, while each tuna RFMO is supported by a scientific committee or staff, comprised of some of the world's finest scientists who study the health of the world's tuna populations, their work is only as good as the completeness and accuracy of the supporting data.

ISSF and its participating companies have resolved to support the tuna RFMO scientists to ensure that their findings and the data underlying them are as accurate and complete as possible. To this end, the companies have committed to provide data that is within their control directly to the RFMO scientific bodies.

As requested by ISSF, the RFMOs have developed a uniform set of minimum standards for information requested from the companies. The standards are provided in the attached table. In addition, the provisions for protection and handling of members' data by the RFMOs are presented. The RFMOs and scientific body of interest herein are the Inter-American Tropical Tuna Commission (IATTC), the International Commission for the Conservation of Atlantic Tuna (ICCAT), the Indian Ocean Tuna Commission (IOTC), and the Secretariat of the Pacific Community (SPC), which provides scientific advice to the Western and Central Pacific Fisheries Commission (WCPFC).

First, the data provided by a company to an RFMO or scientific body continues to be the property of the company, and it is protected from any release or presentation that would reveal the operations of individual companies. This is accomplished in each organization by rules of procedure which indicate that data presented to the public will be an aggregate of data of three or more companies or individuals. Second, the documents, data (in any form including digital) holdings, offices, and property of the RFMOs and their scientific bodies are protected from search and seizure equivalent to that of a foreign government by laws of Spain (ICCAT), France and New Caledonia (SPC), Seychelles (IOTC), and the United States (IATTC). The IATTC and SPC have a MOU in place providing for data sharing to ensure correct compilation and reporting of data for the entire Pacific, and to facilitate analyses of stock status. Access to records of individual companies or operations may not be released to others without the permission of the data provider.

Generally, the data from unloadings/landings are used to determine total catch by species, and in analyses of catches recorded in fishing vessel logbooks and observer records. Statistics on total catch are used in assessments of stock status and are presented in aggregates that include data from all sources. Analyses of catches from fishing vessel records are generally used to estimate catches by area, and to determine if the information in a logbook or observer record should be included in scientific analyses.

Even in cases where RFMO member nations are fully and timely complying with their data provision obligations to the RFMOs, the scientists find that independent provision of data from companies is valuable for their work and for validation of data received from other sources. The IATTC is an excellent case in point. Due to the $100 \%$ observer coverage on purse seine fishing vessels, they have the most robust data set of all of the RFMOs, yet they also have an established process for directly collecting processor and landings data.

The specific information listed below should be compiled and submitted to the RFMO representative. There is no need to submit all data to each RFMO. Rather, the RFMO representing the ocean area of capture should receive the specific trip information. (i.e., for trips in the Eastern Pacific, submit to IATTC; Indian Ocean submit to IOTC, etc).

Information should be complied and submitted for, and within a month of the end of, each calendar quarter. For the initial submission, please submit the data for all of 2009 by January 31, 2010.

The contacts for submission are:
IATTC: Guillermo Compeán (gcompean@iattc.org) with a copy to Michael Hinton (mhinton@iattc.org).
ICCAT: info@iccat.int with a copy to: Victor Restrepo (victor.restrepo@iccat.int)
IOTC: Miguel Herrera (Miguel.Herrera@iotc.org) and Lucia Pierre (Data.Assistant@iotc.org)
SPC/WCPFC: Tim Lawson (TimL@spc.int) and Peter Williams (PeterW@spc.int)
Please contact me if you have any questions.
Thank you in advance for your cooperation and assistance in this very valuable and worthy undertaking.
Yours sincerely,
(signed)

## Information for unloading/landings data to be provided RFMOs or scientific program for each unloading/landing

| Information Requested |
| :--- |
| Unloading directly from fishing vessel |
| Name of fishing vessel |
| Call sign |
| Gear type ${ }^{\text {i }}$ used to capture fish |
| Flag state |
| Start date for unloading to processor |
| End date for unloading to processor |
| Fishing area ${ }^{\text {ii }}$ from which the unloaded catch was taken |
| Date range of operations of catcher vessel(s) for transshipped catch |
| Out turn, or bill of lading, weight of catch by commercial species/size categories ${ }^{\text {iii }}$, by catcher vessel(s) |
| Unloading from carrier vessel (transshipments) |
| Name of vessel |
| Call sign |
| Flag state |
| Start date of unloading at processor |
| End date of unloading at processor |
| Name of catcher vessel(s) and/or processor originating transshipment(s) |
| Date(s) of transfer of fish from catcher vessel(s) by vessel, and/or transfer from processor(s), to carrier |
| Location of transfers(s) (at sea/port name) by transfer |
| Date range of operations of catcher vessel(s) for transshipped catch |
| Out turn, or bill of lading, weight of catch by commercial species/size categories <br> or transshipment(s) by catcher vessel(s), and/or processor(s) |

i For multi-gear vessels, the gear type used to capture the fish
ii Area definitions: Atlantic Ocean, Indian Ocean, eastern Pacific Ocean (IATTC, area east of $150^{\circ}$ ), western Pacific Ocean (west of IATTC area)
iii The commercially identified species, and size category for size-sorted fish

[^0]:    Production model (Logistic) results represent median and $80 \%$ confidence limits based on catch data for (1950-2009) and the joint distribution of bootstraps using each of three alternative combined indices.
    ${ }^{2} 80 \%$ confidence limits, MSY and replacement yield rounded to 100 t .
    ${ }^{3}$ Reports for 2009 should be considered provisional.

[^1]:    ${ }^{1}$ Reference points estimates based on 2007 assessment. Approximately 95\% confidence bounds in the South stock.
    ${ }^{2}$ Reference points estimates based on 2009 assessment. 95\% CI around the reference points were based on estimated 2007 standard errors in the North stock.

[^2]:    ${ }^{1} \mathrm{~F}_{\text {replacement }}$ is the fishing mortality that will maintain the biomass constant from one year to the next. Thus, biomass is expected to grow when $\mathrm{F}<\mathrm{F}_{\text {replacement }}$ and vice-versa

[^3]:    As estimated during the 2000 (Anon. 2001) and 2002 (Anon. 2003) assessments.
    ${ }^{2}$ Catch $_{\text {recent }}$ is the average longline catch for 2000-2004.
    ${ }^{3}$ Estimate of total removals obtained by the Committee.
    ${ }^{4}$ Range of estimates were obtained in the previous assessments, but recent analyses suggest that the lower bound for white marlin should be at least 600 t .

[^4]:    ${ }^{1}$ Results from Bayesian production model with informative priors. These results represent only the uncertainty in the production model fit. This range underestimates the total uncertainty in the estimates of MSY.
    ${ }^{2}$ Some countries have domestic regulations.

[^5]:    Base Case production model (Logistic) results based on catch data 1950-2008.
    Provisional and subject to revision.
    $380 \%$ bias corrected confidence intervals are shown.
    4 Provisional and preliminary, based on production model results that included catch data from 1970-2008.
    5 As of September 29, 2010.

[^6]:    * Current Task I figures (2008 and 2009) where the shaded cells indicate which catches have changed since the assessment.

[^7]:    ${ }^{1}$ Estimated catch used in the 2008 assessments.
    ${ }^{2}$ Task I catch.
    ${ }^{3}$ Range obtained from the Bayesian Surplus Production (BSP) (low) and the Catch-Free Age Structured Production (CFASP) (high) models. Value from CFASP is $\mathrm{SSB} / \mathrm{SSB}_{\mathrm{MSY}}$.
    ${ }^{4}$ Range obtained from BSP (high), CFASP and Age-Structured Production Model (ASPM) (low) models.
    ${ }^{5}$ From BSP and CFASP models (same value). CV is from CFASP model.
    ${ }^{6}$ Range obtained from BSP (high) and CFASP (low) models.

[^8]:    ${ }^{1}$ Estimated catch allocated to the Northwest stock area.
    ${ }^{2}$ Range obtained from age-structured model (Canadian assessment; low) and BSP model (high). Value from Canadian assessment is in numbers; value from BSP in biomass. All values in parentheses are CVs.
    ${ }^{3}$ Range obtained from BSP model (low) and age-structured model (high).
    ${ }^{4}$ Range obtained from BSP model (low) and age-structured model (high).
    ${ }^{5}$ The TAC for the Canadian EEZ is 185 t (MSY catch is 250 t ); the TAC for the USA is 11.3 t .

[^9]:    ${ }^{1}$ Estimated catch allocated to the Northeast stock area.
    ${ }^{2}$ Range obtained from BSP (high) and ASPM (low) models. Value from ASPM model is SSB/SSB MSY . The value of 1.93 from the BSP corresponds to a biologically unrealistic scenario; all results from the other BSP scenarios ranged from 0.29 to 1.05.
    ${ }^{3}$ Range obtained from the BSP and ASPM models (low and high for both models).
    ${ }^{4}$ Range obtained from BSP (low) and ASPM (high) models. The value of 0.04 from the BSP corresponds to a biologically unrealistic scenario; all results from the BSP scenarios ranged from 0.70 to 1.26.
    ${ }^{5}$ In the European Union.

[^10]:    $20 \%$ of active PS between $15-24 \mathrm{~m}$
    $20 \%$ active trawlers
    20\% active LL
    $20 \%$ active BB
