INTERNATIONAL COMIMISSION
for the
CONSERVATION of ATLANTIC TUNAS

REPORT
for biennial period, 2010-11
PART II (2011) - Vol. 2
English version

# INTERNATIONAL COMMISSION FOR THE CONSERVATION OF ATLANTIC TUNAS 

## CONTRACTING PARTIES

(as of 31 December 2011)
Albania, Algeria, Angola, Barbados, Belize, Brazil, Canada, Cape Verde, China, Côte d'Ivoire, Croatia, Egypt, Equatorial Guinea, European Union, France (St. Pierre \& Miquelon), Gabon, Ghana, Guatemala, Guinea (Rep.), Honduras, Iceland, Japan, Korea (Rep.), Libya, Mauritania, Mexico, Morocco, Namibia, Nicaragua, Nigeria, Norway, Panama, Philippines, Russia, Sao Tomé \& Principe, Senegal, South Africa, Sierra Leone, St. Vincent and the Grenadines, Syria, Trinidad \& Tobago, Tunisia, Turkey, United Kingdom (Overseas Territories), United States, Uruguay, Vanuatu, Venezuela

## COMMISSION OFFICERS

| Commission Chairman | First Vice-Chairman | Second Vice-Chairman |
| :--- | :--- | ---: |
| M. MIYAHARA, Japan | M. AGUILAR, Mexico | M. TACKEY, Ghana |
| (since 19 November 2011) | (since 19 November 2011) | (since 19 November 2011) |

## Panel No.

PANEL MEMBERSHIP

| $-1-$ | Angola, Belize, Brazil, Canada, Cape Verde, China, Côte d'Ivoire, Equatorial Guinea, European |
| :---: | :--- |
| Tropical | Union, France (St. Pierre \& Miquelon), Gabon, Ghana, Guatemala, Honduras, Japan, Korea |
| tunas | (Rep.), Libya, Mauritania, Mexico, Morocco, Namibia, Nigeria, Panama, Philippines, Russia, |
|  | Sao Tome \& Principe, Senegal, Sierra Leone, South Africa, St. Vincent \& the Grenadines, | Trinidad \& Tobago, Turkey, United States, Uruguay, Venezuela.

-2- Albania, Algeria, Belize, Brazil, Canada, China, Croatia, Egypt, European Union, France (St.
Temperate Pierre \& Miquelon), Iceland, Japan, Korea (Rep.), Libya, Mexico, Morocco, Norway, Panama, tunas, North St. Vincent and the Grenadines, Syria, Tunisia, Turkey, United States.
-3- Belize, Brazil, European Union, Japan, Mexico, Namibia, Philippines, South Africa, Turkey, Temperate United States, Uruguay.
tunas, South
-4- Algeria, Angola, Belize, Brazil, Canada, China, Côte d'Ivoire, Equatorial Guinea, European Other species Union, France (St. Pierre \& Miquelon), Gabon, Japan, Korea (Rep.), Mexico, Morocco, Namibia, Nigeria, Norway, Sao Tome \& Principe, Senegal, South Africa, St. Vincent \& the Grenadines, Trinidad \& Tobago, Tunisia, Turkey, United Kingdom (Overseas Territories), United States, Uruguay, Venezuela.

## SUBSIDIARY BODIES OF THE COMMISSION

## STANDING COMMITTEE ON FINANCE \& ADMINISTRATION (STACFAD)

STANDING COMMITTEE ON RESEARCH \& STATISTICS (SCRS)
Sub-Committee on Statistics: G. ScotT (United States), Convener
Sub-Committee on Ecosystems: S. Cass-Calay (United States), Convener

## Chair

Côte d'Ivoire

European Union

South Africa

Brazil

## Chair

S. LAPOINTE, Canada (since 15 November 2009)
J. SANTIAGO, EU
(since 8 October 2010)
C. Rogers, United States
(since 18 November 2007)
T. El Ktiri, Morocco
(since 19 November 2011)

## ICCAT SECRETARIAT

## FOREWORD

The Chairman of the International Commission for the Conservation of Atlantic Tunas presents his compliments to the Contracting Parties of the International Convention for the Conservation of Atlantic Tunas (signed in Rio de Janeiro, May 14, 1966), as well as to the Delegates and Advisers that represent said Contracting Parties, and has the honor to transmit to them the "Report for the Biennial Period, 2010-2011, Part II (2011)", which describes the activities of the Commission during the second half of said biennial period.

This issue of the Biennial Report contains the Report of the $22^{\text {nd }}$ Regular Meeting of the Commission (Istanbul, turkey, November 11-19, 2011) and the reports of all the meetings of the Panels, Standing Committees and SubCommittees, as well as some of the Working Groups. It also includes a summary of the activities of the Secretariat and the Annual Reports of the Contracting Parties of the Commission and Observers, relative to their activities in tuna and tuna-like fisheries in the Convention area.

The Report is published in four volumes. Volume 1 includes the Proceedings of the Commission Meetings and the reports of all the associated meetings (with the exception of the Report of the Standing Committee on Research and Statistics-SCRS). Volume 2 contains the Report of the Standing Committee on Research and Statistics (SCRS) and its appendices. Volume 3 includes the Annual Reports of the Contracting Parties of the Commission. Volume 4 includes the Secretariat's Report on Statistics and Coordination of Research, the Secretariat's Administrative and Financial Reports, and the Secretariat's Reports to the ICCAT Conservation and Management Measures Compliance Committee (COC), and to the Permanent Working Group for the Improvement of ICCAT Statistics and Conservation Measures (PWG). Volumes 3 and 4 of the Biennial Report are only published in electronic format.

This Report has been prepared, approved and distributed in accordance with Article III, paragraph 9, and Article IV, paragraph 2-d, of the Convention, and Rule 15 of the Rules of Procedure of the Commission. The Report is available in the three official languages of the Commission: English, French and Spanish.

# AREPORT OF THE STANDING COMMITTEE OF RESEARCH AND STATISTICS <br> (Madrid, Spain, October 3-7, 2011) 

## TABLE OF CONTENTS

1. Opening of the meeting ..... 1
2. Adoption of Agenda and arrangements for the meeting ..... 1
3. Introduction of Contracting Party delegations ..... 1
4. Introduction and admission of observers ..... 2
5. Admission of scientific documents ..... 2
6. Report of Secretariat activities in research and statistics ..... 2
7. Review of national fisheries and research programs ..... 2
8. Executive Summaries on species: ..... 10
YFT-Yellowfin ..... 11
BET-Bigeye. ..... 26
SKJ-Skipjack ..... 42
ALB-Albacore ..... 57
BFT-Bluefin East-Med ..... 77
BFT-Bluefin West ..... 83
BUM/WHM-Blue marlin/White marlin ..... 103
SAI-Sailfish ..... 118
SWO-ATL-Swordfish ..... 126
SWO-MED-Swordfish ..... 144
SBF-Southern Bluefin ..... 153
SMT-Small Tunas ..... 154
SHK-Sharks ..... 167
9. Report of Inter-sessional meetings ..... 181
9.1 Workshop on the use of R Tools in the Data Preparatory Work ICCAT-SCRS. ..... 181
9.2 Working Group on the Organization of the SCRS ..... 181
9.3 2011 Blue Marlin Stock Assessment Session and White Marlin Data Preparatory Meeting ..... 181
9.4 Inter-sessional Meeting of the Sub-Committee on Ecosystems ..... 182
9.5 Tropical Tuna Species Group Intersessional Meeting on the Ghanaian Statistics Analysis (Phase II) ..... 182
9.6 Sharks Data Preparatory Meeting to Apply Ecological Risk Assessment ..... 182
9.7 Joint Meeting of the ICCAT Working Group on Stock Assessment Methods and the Bluefin Tuna Species Group to Analyze Assessment Methods Developed Under the GBYP and Electronic Tagging ..... 183
9.8 South Atlantic Albacore and Mediterranean Albacore Assessment Sessions ..... 183
9.9 Yellowfin stock assessment session ..... 183
10. Report of Special Research Programs ..... 183
10.1 Atlantic Wide Research Programme for Bluefin tuna (GBYP) ..... 183
10.2 Enhanced Research Program for Billfish ..... 183
11. Report of the Sub-Committee on Statistics ..... 183
12. Report of the Sub-Committee on Ecosystems ..... 184
13. A Consideration of Implications of the Working Group on the Organization of the SCRS that met in Madrid in February ..... 184
14. A Consideration of Implications of the Future of ICCAT meeting in Madrid this May ..... 185
15. A Consideration of Implications of the third meeting of Tuna RFMOs held in July in La Jolla, USA ..... 185
16. Consideration of plans for future activities ..... 185
16.1 Annual Work Plans ..... 185
16.2 Inter-sessional meetings proposed for 2012 ..... 185
16.3 Date and place of the next meeting of the SCRS ..... 188
17. General recommendations to the Commission ..... 188
17.1 General recommendations to the Commission that have financial implications ..... 188
17.2 Other recommendations ..... 190
18. Responses to Commission's requests ..... 192
18.1 Develop a Limit Reference Point (LRP) for the North Atlantic swordfish stock Rec. [10-02] ..... 192
18.2 Review of North Atlantic swordfish data requested under [Rec. 10-02] ..... 193
18.3 Exploring operationally viable technologies and methodologies for determining the size and biomass at the points of capture and caging [Rec. 10-04] ..... 194
18.4 Reporting on the scientific aspects of the national observer programmes on the basis of the information provided by CPC [Rec. 10-04] ..... 194
18.5 Completing the sharks identification guide [Rec. 10-06] ..... 195
18.6 Evaluating the information provided by CPCs on alternative scientific monitoring approach to observer program to apply in vessels less than 15 m . [Rec. 10-10] ..... 195
18.7 Continuation of the evaluation of data elements pursuant to [Rec. 05-09] ..... 195
18.8 Response to the Commission Regarding Rec. 10-09 ..... 195
19. Other matters ..... 196
20. Adoption of the report and closure ..... 196
Appendix 1. SCRS Agenda ..... 197
Appendix 2. List of Participants ..... 199
Appendix 3. List of 2011 SCRS Documents ..... 209
Appendix 4. Work Plans of the Species Groups for 2012 ..... 221
Appendix 5. Atlantic-wide Research Programme for Bluefin Tuna (GBYP) Activity Report For 2011 (Phase 2) ..... 231
Appendix 6. ICCAT Enhanced Research Program for Billfish ..... 237
Appendix 7. Report of the Meeting of the Sub-Committee on Statistics ..... 242
Appendix 8. Report of the Meeting of the Sub-Committee on Ecosystems. ..... 265
Appendix 9. References ..... 267

# REPORT OF THE <br> STANDING COMMITTEE ON RESEARCH AND STATISTICS (SCRS) <br> (Madrid, Spain - October 3 to 7, 2011) 

## 1. Opening of the meeting

The 2011 Meeting of the Standing Committee on Research and Statistics (SCRS) was opened on Monday, October 3, at the Hotel Velázquez in Madrid by Dr. Josu Santiago, Chairman of the Committee. Dr. Santiago welcomed all the participants to the annual meeting.

The ICCAT Executive Secretary, Mr. Driss Meski, addressed the meeting and welcomed all the participants to Madrid. The Executive Secretary reminded the relevance of the work conducted by the Committee and the important role of the SCRS in providing scientific advice to the Commission. Mr. Meski recognized that as the stock status becomes complicated our Commission is requested to provide more clarifications. Mr. Meski highlighted that the SCRS work is very much appreciated by our Commission and on the international level, even though participation of the national scientists has shown a sharp decline in recent years.

Finally, the Executive Secretary hoped that the delegations that have undergone a reduction in their activities will renew their interest by participating more in the work of the SCRS so as to assure that our Committee has the reputation it deserves and wished every success in the work of our Committee.

## 2. Adoption of Agenda and arrangements for the meeting

The Tentative Agenda was reviewed and adopted (attached as Appendix 1). Stock assessments were carried out this year on South Atlantic and Mediterranean albacore (ALB-Med and ALB-S), blue marlin (BUM) and yellowfin tuna (YFT).

The following scientists served as rapporteurs of the various species sections (Agenda Item 8) of the 2011 SCRS Report.

| Tropical tunas- General | J. Pereira |
| :--- | :--- | :--- |
| YFT $-\quad$ Yellowfin tuna | C. Brown |
| BET - Bigeye tuna | D. Die |
| SKJ - Skipjack tuna | D. Gaertner |
| ALB - Albacore | H. Arrizabalaga, J. Ortiz de Urbina (Med) |
| BFT - Bluefin tuna | C. Porch (W), J.M. Fromentin (E) |
| BIL - Billfishes | F. Arocha |
| SWO - Swordfish | J. Neilson, P. Travassos (Atl.), G. Tserpes (Med.) |
| SBF - Southern bluefin |  |
| SMT - Small tunas | N. Abid |
| SHK - Sharks | A. Domingo |

The Secretariat served as rapporteur for all other Agenda items.

## 3. Introduction of Contracting Party delegations

The Executive Secretary introduced the 19 Contracting Parties present at the 2011 meeting: Brazil, Canada, Cape Verde, China, Côte d'Ivoire, Croatia, European Union, Ghana, Japan, Korea, Mexico, Morocco, Norway, Russian Federation, Senegal, Turkey, United Kingdom (Overseas Territories), United States and Uruguay. The List of Participants at the Species Groups Meetings and the Plenary Sessions is attached as Appendix 2.

## 4. Introduction and admission of observers

Representatives from the following Cooperating non-Contracting Party, Entity, or Fishing Entity (Chinese Taipei), intergovernmental organizations (General Fisheries Commission for the Mediterranean-GFCM), and
non-governmental organizations (Birdlife International, Federation of Maltese Aquaculture Producers-FMAP, Federation of European Aquaculture Producers-FEAP, Fundatun, Greenpeace, Institute for Public KnowledgeIPK, International Seafood Sustainability Foundation-ISSF and The Pew Environmental Group were admitted as observers and welcomed to the 2011 SCRS (see Appendix 2).

## 5. Admission of scientific documents

The Secretariat informed the Committee that 182 or scientific papers had been submitted at the various 2011 inter-sessional meetings. However, the Secretariat noted that a considerable number of documents (34), presented during the meetings were not provided later in the standard format for SCRS documents.

Besides the scientific documents, there are 11 reports of inter-sessional meetings and Species Groups, 28 Annual Reports from the Contracting Parties, and non-Contracting Cooperating Parties, Entities and Fishing Entities, as well as various documents by the Secretariat. The List of SCRS Documents is attached as Appendix 3.

## 6. Report of Secretariat activities in research and statistics

The Secretariat presented the "Secretariat Report on Statistics and Coordination of Research 2011" which summarizes activities in 2011. This document was discussed at length during the Species Groups meetings and during the session of the Sub-Committee on Statistics. The first eight tables of this document point out the improvements in data submission and the use of the electronic forms. This report also notes the Secretariat's efforts to implement last year's recommendations from the Commission and SCRS concerning the implementation of the Data Confidentiality policy and it's implication for the ICCAT database management and organization.

A comment was made to extend the presentation of the catalog of data submitted to include by-catch species in addition to the main tuna species and the three shark species commonly presented. The Secretariat indicated that this proposal should be presented to the Sub-Committee on statistics for its approval.

A summary of the activities carried out by the ICCAT/Japan Data Management and Improvement Project (JDMIP) was presented (ICCAT, 2012, in press). This project continues to support port sampling developed in Tema (Ghana) and the eastern Caribbean (Venezuela). This program has also made financial contributions towards the participation of scientists from developing countries to SCRS meetings.

Likewise, the Secretariat informed of the activities carried out in 2011 in relation to publications, noting that in 2011 a forth volume has been added to the Biennial Report which includes the reports from the Secretariat and other committees.

A protocol for the allocation of capacity building and data improvements was discussed during the SubCommittee on Statistics. The protocol defines three major areas for funding requests and provides guidelines on the proposal request, evaluation, awarding and deadlines for all requests.

## 7. Review of national fisheries and research programs

## Brazil

In 2010, the Brazilian tuna longline fleet consisted of 96 vessels. Of these 96 boats, 92 were national and 4 were foreign chartered vessels. The total number of vessels increased by about $10 \%$ from 2009, when 86 vessels operated. The number of bait-boats operating in 2010 was 41, which all of them are national boats. The number of purse seiner boats decreased from 8 in 2009 to 5 in 2010.

The Brazilian catch of tunas and tuna-like fishes, including billfishes, sharks, and other species of minor importance, was $33,419.9 \mathrm{t}$, in 2010, representing a decrease of $16.6 \%$, from 2009. Despite the catch estimates for the bait-boat fishery are still preliminary, in 2010, the majority of the catch again was taken by this fishery ( $14,475.2 \mathrm{t}$; $43.0 \%$ ), with skipjack tuna being the most abundant species ( $87.9 \%$ of the baitboat catches). Yellowfin tuna was the second dominant species in the bait-boat fishery, with a total catch of 627.3 t .

The total catch of the tuna longline fishery was $12,349.4$ t, which was $58.3 \%$ higher than 2009 , with dolphin fish being the most abundant species, accounting for $41.4 \%$ of the longline catches, following by swordfish ( $21.5 \%$ ) and blue shark $(12.1 \%)$. Yellowfin tuna was the fourth most abundant species in the Brazilian longline fishery, accounting for $9.2 \%$. The total catch of white marlin and blue marlin was, respectively, 35 t and 130 t , representing a decreasing trend of $32.7 \%$ and $12.7 \%$ from 2009, respectively.

Part of the Brazilian catches resulted again from the fishing activities of small scale fishing boats based mainly in Itaipava-ES (southeast coast) which includes several target species with different gears, including longline, handline, trolling and other surface gears. In 2010, this fleet caught 5,813.0 t of fish, of which dolphin fish contributed with $42.5 \%$. Yellowfin was the second most caught species with $28 \%$ following by the skipjack tuna, which accounts with $12.5 \%$ of the catches taken by this fishery.

Besides the catch and effort data regularly collected from Brazilian tuna fisheries, in 2010, around 5,000 fishes were measured at sea and while landing. The main fish species measured were: dolphin fish; blue shark; yellowfin; bigeye; swordfish; sailfish; white marlin; and blue marlin.

Brazilian research efforts continued on tunas, billfish and sharks, as well as on the incidental catches of seabirds and sea turtles, aiming at monitoring by-catch and testing mitigation measures.

## Canada

In 2010, Canada landed 1,346 t of swordfish in 2010, 505 t of bluefin tuna, 14 t of albacore tuna, 103 t of bigeye tuna, and 166 t of yellowfin tuna. Canada also landed 41 t of shortfin mako, and 83 t of porbeagle. When compared with 2009, these amounts are generally similar.

Bluefin tuna research focused on post-release survival, migration studies, understanding the influences of ocean environment on catch rates and cooperation with the GBYP to improve our understanding of the age and stock origin of the catch in Canadian waters. Swordfish research targeted improved understanding of stock structure, and documenting the recovery of swordfish in the Atlantic, along with many other scientists from the SCRS. Shark research has been directed to improved estimates of post-release mortality, determining spawning areas, and improving biological statistics in support of improved assessments. More details of the Canadian research program may be found in the Annual Report of Canada.

## Cape Verde

The Cape Verde tuna fleet in 2010 was comprised of 101 operational vessels over 11 meters. The catch data on tunas and tuna/like species in 2010 are provisional and estimated at 13.304 tonnes, caught mainly by purse seine and pole and line in the industrial or semi-industrial fishery and with hand line in artisanal fishing.

In Cape Verde, at the national level, there was no industrial fishing vessel targeting sharks since 2007. Shark catches are caught incidentally. Due to the fragility of our surveillance, sharks are often part of the by-catches of the foreign longline fleet that fishing in the Cape Verde EEZ.

Sport fishing has been, over time, an important activity for economic, cultural and political development, but unfortunately this fishery is still not monitored.

Billfishes are caught in Cape Verde waters, mainly by EU vessels and by sport fishing. The authorized foreign fleet, fishes in the Cape Verde EEZ based on fishing agreements or contracts. The vessels mostly pertain to European Union and Asian countries.

The objective of the research is to formulate recommendations for the optimal and sustainable exploitation of the aquatic living resources, taking into account the economic and social objectives established in the policy on development, but without neglecting the protection of the environment, the conservation of the resources and the preservation of nature, particularly the biological marine heritage. Research on fishing and the environment and socio-economic studies are thus instruments of considerable importance for the development of fishing. The data compiled are regularly transmitted to the ICCAT Secretariat, thereby contributing to the updating of statistics and to the ICCAT stock assessments.

The implementation of the ICCAT conservation and management measures is carried out through the Fishing Management Plan, which was updated in 2009.

## China

Longline is the only fishing gear used by the Chinese fishing fleet to fish tunas in the Atlantic Ocean. Thirty Chinese tuna longliners operated in 2010, with a total catch of $6,873 \mathrm{t}$ including tuna, tuna-like species and sharks (in round weight), 515.5 t more than that of 2009 ( $6,357.5 \mathrm{t}$ ). The target species were bigeye tuna and bluefin tuna, of which catches amounted to $5,489 \mathrm{t}$ and 38.22 t , in 2010, respectively. Bigeye tuna was the major target species in Chinese catch, accounting for $79.9 \%$ of the total, however, it was 516 t more than that of 2009 ( $4,973 \mathrm{t}$ ). Yellowfin tuna, swordfish and albacore were taken as by-catch. The catch of yellowfin tuna decreased from 462 t in 2009 to 426.9 t in 2010. The catch of swordfish was 369.1 t , with a tiny decrease from the previous year ( 383 t in 2009). The catch of albacore was 239.6 t , which represented a $106.6 \%$ increase from the previous year.

The data compiled, including Task I and Task II as well as the number of fishing vessels, have been routinely reported to the ICCAT Secretariat by the Bureau of Fisheries (BOF), Ministry of Agriculture of the People’s Republic of China. China has carried out a national scientific observer program for the tuna fishery in ICCAT waters since 2001. Two observers have been dispatched on board two Chinese Atlantic tuna longline fishing

 bluefin tuna) since September, 2010. Data of target species and non-target species (sharks, sea turtles, especially) were collected during the observation.

In terms of implementation of the relevant ICCAT conservation and management measures, the BOF requires all fishing companies operating in the Atlantic Ocean to report their fisheries data on a monthly basis to the Branch of Distant Water Fisheries of China Fisheries Association and the Tuna Technical Working Group in order to comply with the catch limits. The BOF has established a fishing vessel management system, including the issuance of licenses to all the approved Chinese fishing vessels operating on the high seas of world oceans. The Chinese high seas tuna fishing fleet has been required to be equipped with a VMS system since October 1, 2006. The BOF has strictly followed the National Observer Program and the ICCAT Regional Observer Program for transshipment at sea.

## Croatia

Total Croatian catch of bluefin tuna in 2010 in commercial fisheries was 385.69 metric tons ( t ). The bluefin tuna were predominantly transferred into farming cages ( 353.764 t ; $91.7 \%$ ) and $16.14 \mathrm{t}(4.19 \%)$ were landed. Bluefin catches were mostly realized by purse seiners ( 369.54 t ; 95.81\%), while the remaining was caught using hook and line gears. A difference of 15.77 tons (4.1\%) has been registered between the purse seine catch ( 369.54 t ) and caging ( 353.764 t ). The difference is due to the fact that counting and recording of transfers to farm is performed in conditions which allow better results. However, Croatia closed the fishery based on the catch reported and authorized.

The total Croatian catch of Mediterranean (Adriatic) swordfish in 2010 amounted to $5,740 \mathrm{~kg}$.
Research was continued on issues of growth and reproductive biology of bluefin tuna. National sampling program targeting bluefin tuna harvested from aquaculture facilities has been carried out. The research activities are under way aiming to estimate the impact of increased abundance of small bluefin tuna in the Adriatic on small pelagic fishery. Preliminary research on the use of stereoscopic camera for bluefin sizing and counting has been carried out.

Croatia has adopted the Regulation on catch, farming and trade of bluefin tuna that includes all provisions of the relevant ICCAT Recommendations and transposes them into national legislation in full. Croatia has implemented the ROP programme in full accordance with the provisions of the relevant ICCAT Recommendations.

## European Union

The European Union fleets caught 192,000 tonnes (t) in 2010, which is close to $40 \%$ the total catches of ICCAT. These 2010 catches increased slightly as compared to the $155,000 \mathrm{t}$ in 2007, this following the increasing catches of tropical tunas and the return to the Atlantic of the purse seiners that operated in the Indian Ocean. These catches fall far short of the $300,000 \mathrm{t}$. that were landed in the early 1990s for the same EU countries. Eight EU countries carry out tuna fishing in the Atlantic and the Mediterranean, whose catches in descending order in

2010 were: Spain (116,000 t), France ( 43.000 t), Portugal (20,500 t) with high catches of skipjack in 2010, Italy ( $9,300 \mathrm{t}$ ), Greece ( $1,800 \mathrm{t}$ ), Ireland ( 900 t ), Malta and Cyprus. The major species caught by the EU countries in 2010 were skipjack, which sharply increased ( 68,900 t.), yellowfin ( $46,500 \mathrm{t}$ ), swordfish ( $21,100 \mathrm{t}$ ) and bigeye $(18,300 \mathrm{t})$, albacore ( $17,100 \mathrm{t}$ ), and bluefin tuna ( $6,060 \mathrm{t}$ ). It is noted that while the 2010 catches of tropical tunas have been increasing slightly every year since 2007, the catches of albacore and swordfish are stable, and bluefin tuna catches are declining. All the traditional fishing gears are active in the EU: purse seiners, baitboats, longliners, hand lines, troll, driftnets, harpoons, pelagic trawl, traps and sport fishing.

Since 2001, the EU also largely and routinely finances the collection of biological data and a number of research projects on the tunas of all its member countries. Biological sampling of the tropical tunas catches from European purse seiners is also carried out routinely at the Abidjan canneries and, since 2008, in the French Antilles artisanal fisheries. The Task I and II statistical data submitted to ICCAT in 2011 by the EU countries are overall complete and in accordance with the ICCAT rules. It should be noted that the EU also supports observer programmes on various fleets, the tropical purse seiners with about $10 \%$ of the fishing effort monitored by observers, and since 2009, 100\% of the fishing days observed on purse seiners fishing bluefin tuna in the Mediterranean. Also of note again in 2011 is the considerable financial support from the EU towards the ICCAT GBYP intensive research on bluefin tuna.

The active participation of European scientists at all the ICCAT scientific meetings and the large number of SCRS documents co-authored by EU scientists covering all ICCAT research areas and species was also noted. EU countries also carry out considerable research of a more fundamental nature on tunas on, for example, ecosystems, the reduction of by-catches, tuna-environment relations, tuna behavior, FADs, spawning and reproduction of larvae and juvenile bluefin tuna, marine protected areas used the for tuna resources, reduction of unwanted by-catches, modeling of high seas pelagic ecosystems, etc. The participation of EU countries is, for example, active in the framework of the CLIOTOP/GLOBEC programme which has broad objectives that are multi-disciplinary and worldwide, and which are aimed at carrying out better modelling of the sustainable exploitation of the tuna resources based on the environment and the ecosystems.

## Ghana

The tuna industry in Ghana comprises skipjack (Katsuwonus pelamis), yellowfin (Thunnus albacares) and bigeye tuna (Thunnus obesus). Twenty-two (22) baitboats and 15 purse seiners are currently fishing within the EEZ of Ghanaian coastal waters and beyond and exploit these tuna species amongst other minor tuna-like species such as the black skipjack (Euthynnus alletteratus). During the year under review, skipjack catches were the highest (69\%) followed by yellowfin (16\%) and bigeye (9\%), respectively.

Both fleets employ Fish Aggregating Devices (FADs) in fishing and collaborate extensively sharing their catch during fishing operations. Over $80 \%$ of catches are conducted off FADs. Catches for the year 2010 rose slightly to $77,876 \mathrm{t}$, from $66,470 \mathrm{t}$ in 2009. All data for 2010 were submitted via the AVDTH format during the intersessional meeting on Ghana's statistics in May 2011.

Recent improvements in sampling, coupled with the provision of more logbook information from the fishery, has contributed to a better understanding of the spatio-temporal distribution of the species. It is envisaged that further synthesis of the database on Ghana since 1980-2010 which is ongoing will give a clear sampling strategy to improve the catch and species composition of the entire catch in relation to innovations observed in the fishery.

An observer programme was organized in March-May 2010 on board four purse seine vessels with the aim of training officers on proper methods of estimating catches and filling out of information in logbooks. Further in early 2011, four observers sponsored by the JDMIP project were deployed on purse seiners. Reports have been duly sent to the ICCAT Secretariat. Increased port sampling was also carried out during the months of May-July 2011 also sponsored by the JDMIP.

Beach sampling of billfishes under the ICCAT Enhanced Research Programme for Billfish continued off the western coast of Ghana from artisanal drift gill operators with slight declines in catches.

## Japan

Longline is the only tuna-fishing gear deployed by Japan at present in the Atlantic Ocean. The final coverage of the logbook from the Japanese longline fleet has been $90-95 \%$ before 2009. The current coverage for 2010 is estimated to be about $90 \%$. In 2010, fishing days was about 22,000 days, which was about $80 \%$ of average value in recent ten years. The catch of tunas and tuna-like fishes (excluding sharks) is estimated to be about $30,000 \mathrm{t}$,
which are about $90 \%$ of the past ten years average catch. The most important species was bigeye representing $55 \%$ of the total tuna and tuna-like fish catch in 2010. The next dominant species was yellowfin occupied $17 \%$ in weight and third species was swordfish (9\%). Observer trips on longline boats in the Atlantic were conducted and total of about 600 fishing days were monitored. In addition to the logbook submission mentioned above, Fisheries Agency of Japan (FAJ) has set catch quotas for western and eastern Atlantic bluefin as well as for northern, southern Atlantic swordfish, blue marlin, white marlin and bigeye tuna, and has required all tuna vessels operating in the Atlantic Ocean to submit catch information every day (bluefin tuna) and ten-day (other tunas) period by radio or facsimile. All Japanese longline vessels operating in the Convention Area has been equipped with satellite tracking devices (VMS) onboard. In accordance with ICCAT recommendations, the FAJ has taken necessary measures to comply with its minimum size regulations, time area closures and so on by a Ministerial Order. Each species statistical or catch document programs have been conducted. Records of fishing vessels larger than 24 meters in length overall (LSTLVs) have been established. The FAJ has dispatched patrol vessels to the North Atlantic to monitor and inspect Japanese tuna vessels and also observe fishing activities of other nations' fishing vessels, and inspected landings at Japanese port to enforce the catch quotas and minimum size limit. A prior permission from the FAJ has been required in the case that Japanese tuna longline vessels transship tuna or tuna products to reefers at foreign ports or at sea.

## Korea

In 2010, a total of 16 Korean longliners and two purse seiners were operated in the ICCAT area, of which three longliners and one purse seiner were operated under the chartering arrangement with Côte d'Ivoire, and caught a total of $3,423 \mathrm{t}$, which was a decrease by $11.3 \%$ compared to the previous year. Almost $95.7 \%$ of the total catch were from three major species, of which bigeye tuna catch was $2,657 \mathrm{t}$ ( $77.6 \%$ ), yellowfin tuna 380 t ( $11.1 \%$ ) and albacore 240 t ( $7.0 \%$ of the total). It was notable that no bluefin tuna catch was made in 2010 although one purse seiner was operated in the Mediterranean. Korean longliners have mainly operated in the tropical area of the Atlantic Ocean and targeted bigeye tuna and yellowfin tuna. Fishing season was throughout the year from January to December in 2010 in the central Atlantic Ocean $\left(15^{\circ} \mathrm{N} \sim 15^{\circ} \mathrm{S}, 10^{\circ} \mathrm{E} \sim 50^{\circ} \mathrm{W}\right)$. Compared to the previous year, longline fishing area was slightly extended further south and eastward. However, the fishing grounds have fluctuated every year depending on the fishing and oceanographic conditions for target species, with main fishing grounds located in statistical area 34 of the Atlantic Ocean. The National Fisheries Research and Development Institute (NFRDI) has carried out routine scientific monitoring work over the past years. The monitoring was for the collection of catch and fishing effort statistics from the Korean tuna longliners and purse seiners operated in the Atlantic Ocean. The requested Task I and Task II data were already provided to the ICCAT Secretariat. The data coverage for longline fishery was $65.1 \%$ of total catch in 2010. There are two sources of statistical data collection. The Korea Overseas Fisheries Association (KOFA) collects total catches by gear from Korean tuna industries, which are used as the official total catch that cover all tunas and tuna-like species. NFRDI collects logsheet sampling data from fishing vessels. The logsheet contains operation location, catches by species, number of hooks and sets, etc. The estimates of annual catch for the ICCAT area presented in this report are made by cross-checking the logsheet data and the official total catch. Korea began developing its observer program for distant-water fisheries including tuna fisheries in 2002. In 2010, the NFRDI’s observer program deployed 13 trained observers who carried out 16 trips on Korean distant-water fishing vessels in the major oceans including the Antarctic Ocean. For tuna fisheries in the Atlantic, one observer was deployed on the Korean tuna longline vessel that operated in the central Atlantic. To help with the identification of the species of seabirds, sea turtles and sharks incidentally caught by tuna longline and purse seine fishing, guide books and posters summarizing information on these species have been distributed to fishing vessels along with the bycatch logbook sheet since 2008.

## Mexico

Fishing for yellowfin tuna (Thunnus albacares) in the Gulf de Mexico was carried out by mid-water vessels using longline. In this activity besides catching the target species, other species are also caught incidentally, such as: skipjack tuna (Katsuwonus pelamis), bigeye tuna (Thunnus obesus), Atlantic bluefin tuna (Thunnus thynnus), among others. Yellowfin tuna fishing is carried out throughout the year, with the major catches taken in the months of May, June and July. This fishery has certain economic importance at the national as well as the international level, since the export of fresh yellowfin tuna has been one of the important activities in the fishing sector and it has an important place in the economy. The total number of vessels that have maintained a continuous fishing activity has remained between 25 and 32 vessels during the 2001-2010 period. On the other hand, the total catches of yellowfin tuna and similar species amounted to $1,177 \mathrm{t}$ in 2010 , which was a decrease of $21 \%$ compared to 2009 . The Instituto Nacional de Pesca-INAPESCA (National Fishing Institute) is in charge of carrying out the scientific research on these fishing resources, besides having the responsibility for the
research and collection of statistics on longline tuna fishing in the Gulf of Mexico. The monitoring of this fishery has been strengthened thanks to the Programme of on-board observers who register biological, fishery, and fishing method information with observer coverage on each fishing trip.

## Morocco

The fishing of tuna and tuna-like species attained a production of 10,722 metric tons ( t ) in 2010 compared to $13,956 \mathrm{t}$ in 2009, i.e. a decrease of about $23 \%$ in terms of volume.

The major species caught along the Moroccan coasts are bluefin tuna, swordfish, bigeye tuna, yellowfin tuna, albacore, small tunas, and some shark species.

The collection of statistical data on catch and effort data is carried out in an exhaustive manner by the fisheries administration structures, such as the Département des Pêches (Department of Fishing) and the Office National des Pêches (National Office of Fishing), which are all along the Atlantic and Mediterranean coasts of Morocco. Monitoring of the export of fishing products is also carried out by the Office des Changes (the Currency Exchange Office).

With regard to the scientific work, the Institut National de Recherche Halieutique-INRH (National Institute of Fisheries Research), through its Regional Centers (of which there are five) covering the entire Moroccan coast, reinforces the collection of biological data on the major species (bluefin tuna and swordfish). The Regional Center of the INRH in Tangiers serves as coordinator of the collection of all these data. In recent years, the monitoring of other species has been started, particularly tropical tunas (bigeye tuna among others), with an extension of the research work towards areas located to the south of Morocco.

Considerable progress has also been reported regarding the collection of biological data, as noted by the series of scientific documents as well as the Task II databases, submitted by Moroccan scientists at the various SCRS meetings for purpose of stock assessments on tunas.

## Norway

Approximately 100 kg of Atlantic bonito (Sarda sarda) were landed and measured in Norway in 2010. A report entitled: "Atlantic bonito in Nordic waters: biology, distribution and feeding" has been written. There have been no catches and observations of Atlantic bluefin tuna (Thunnus thynnus) and Atlantic swordfish (Xiphias gladius) in Norway in 2010. Norway continuously works on historical data on tuna and tuna like species, and aims to put the data on these species into an ecosystem perspective. During 2010 new historical data on Atlantic bluefin tuna were found after considerable search in various places along the coast of Norway. The search for bluefin tuna material resulted in Task II data (weight, date of catch and catching area) from a total of 14,839 individuals during the time period 1950-1954. Norway participated in all major international scientific meetings concerning Atlantic bluefin tuna in 2010.

## Russia

The fishery. In 2010 and 2011 the specialized purse seine tuna fishery was not carried out by Russian flag vessels. The trawl fishery vessels caught 605 t of tunas and 1042 t of bonito as by-catch from the Central-East Atlantic Ocean during 2010. In the first half of 2011, the trawl fishery vessels caught 640 t of tunas and 968 t of bonito.

Scientific research and statistics. In 2010, observers from AtlantNIRO collected biological material for tunas on board the trawlers in the Central-East Atlantic Ocean (the area SJ71 according to ICCAT classification). The fish length and weight were measured, fish sex, gonads maturity stage and stomach fullness index were determined. The species of the group "little tunas" occurred in trawls as by-catch in amounts from few a individuals to several tens. Material on frigate tuna, bullet tuna, black skipjack and bonito was collected from 4,625 specimens for mass measurements and 2,738 specimens for biological analyses.

Implementation of ICCAT conservation and management measures. During the fishery in the areas where tunas and tuna-like species occur in catches, the ICCAT requirements and recommendations concerning restrictions in the tuna fishery and a ban imposed on fishing quoted species were observed.

## Senegal

In 2010, the Senegalese industrial tuna fleet was comprised of 6 baitboats that mainly fish yellowfin tuna (Thunnus albacares), bigeye tuna (Thunnus obesus) and skipjack tuna (Katsuwonus pelamis), and 1 longline vessel that targets swordfish. Furthermore, some artisanal fisheries (hand line, pole and line and purse seine) and the sport fishery catch billfishes (marlins, swordfish and sailfish) and small tunas (Atlantic black skipjack, mackerel, bonito, frigate tuna, etc.).

The total Senegalese baitboat catch in 2010 is estimated at 4,606 tonnes ( $1,168 \mathrm{t}$ of yellowfin tuna, 2,412 t of skipjack tuna, 844 t of bigeye). Catches have shown a decline as compared to 2009 ( $6,720 \mathrm{t}$ ). This reduction is due to the decrease in fishing effort that went from 1,574 fishing days in 2009 to 1,220 in 2010. Longline catches in 2010 are estimated at 312 t ( 590 t in 2009). The catches are comprised mainly of swordfish, sharks and billfishes. As regards the artisanal fisheries, the catches of small tunas and tuna-like species reached $8,719 \mathrm{t}$. Catches have shown an increase as compared to ( $5,315 \mathrm{t}$ ). With regard to sport fishing, catches are estimated at 288 t in 2010 with an effort of 682 fishing trips.

Regular monitoring of the tuna fishing activities is assured by the CRODT team in place at the port of Dakar. The work consists of the collection of statistics on catches and fishing effort. This work is supplemented by information from different sources (factories, boat owners, Directorate of Marine Fishing, etc.). Some multispecies sampling is also carried out on industrial and artisanal fishing. Thanks to funds from the Enhanced Research Program on Billfish (EPBR), sampling of the billfish catches, effort and sizes has been intensified at the major landing centers of the artisanal fishery.

## Turkey

During the course of 2010, the total catch of tuna and tuna-like fishes amounted to $10,546 \mathrm{t}$. In 2010, Turkey’s total catches of bluefin tuna, albacore, Atlantic bonito and swordfish were $409.377 \mathrm{t}, 402 \mathrm{t}, 9,401 \mathrm{t}$, and 334 t , respectively. All bluefin catch was caught by purse seiners, the majority of which have an overall length $30-50 \mathrm{~m}$ and 200-300 GRT. The fishing operations were conducted intensively off Antalya Bay and in the region between Antalya Gazi Paşa and Cyprus. In the Mediterranean, fisheries were conducted in the region between CyprusTurkey and in the region Cyprus-Syria. The highest bluefin tuna catch amount was obtained in June. Recommendations and resolutions imposed by ICCAT were transposed to national legislation and implemented. All conservation and management measures regarding bluefin tuna fisheries and farming are regulated by national legislation through notifications, considering ICCAT's related regulations. The Fisheries Information System has been updated in order to meet the requirements of data exchange at the national and regional levels. Major research activities in 2010 focused on albacore and swordfish.

## United States

Total (preliminary) reported U.S. catch of tuna and swordfish, including dead discards, in 2010 was 9,190 tons ( t ), a decrease of about $5 \%$ from 9,632 t in 2009. Estimated swordfish catch (including estimated dead discards) slightly decreased from $2,878 \mathrm{t}$ in 2009 to $2,845 \mathrm{t}$ in 2010, and provisional landings from the U.S. fishery for yellowfin slightly decreased from 2,788 tons in 2009 to 2,648 tons in 2010. U.S. vessels fishing in the northwest Atlantic caught in 2010 an estimated 925 t of bluefin, a decrease of 303 t compared to 2009. When compared to the levels in 2009, provisional skipjack landings decreased by 65 t to 54 t in 2010, estimated bigeye landings increased by about 157 t to an estimated 673 t in 2010, and estimated albacore landings increased by 140 t to 328 t in 2010.

In 2010, the United States continued research on several tuna and tuna like species in several areas such as genetics, age and growth, tagging, habitat utilization, and assessment modeling among others. The U.S. Atlantic tagging program continued in 2010 and it tagged and released 1,865 billfishes (including swordfish) and 431 tunas during the year. The U.S. Pelagic Observer Program in 2010 had a target coverage of $8 \%$ of the sets of the fleet; however, the expanded observer coverage in the Gulf of Mexico during the bluefin tuna spawning season continued this year observing approximately $58 \%$ of the longline sets during this period. The bottom longline observer program was also active from January to December 2010, and total of 161 hauls on 105 trips were observed.

## Uruguay

In 2010 fishing effort in the tuna fleet was reduced. The majority of the vessels were less than 27 m in length and target mainly swordfish and tunas. The total catch (preliminary) landed and reported in 2010 was approximately 654 tons.

Various activities were carried out in 2010 related to statistics, research and management. Some of these activities are carried out jointly with other national and international institutions. In 2010, independent research continued on board the DINARA research vessel to collect more detailed information on the pelagic oceanic species, experiments on mitigation measures, etc.

The research was carried out mainly on information from the Observers Programme (PNOFA) and during 2010 data obtained on the research vessel were integrated. PANOFA covered part of the activity of the national fleet in 2010 and $100 \%$ of the deep longline fleet. The tagging program continued and approximately 100 fish were tagged. Uruguay collaborated in various inter-sessional meetings presenting papers for the stock assessments and the data preparatory meetings (bigeye tuna, blue marlin, sharks, ecosystems, etc.).

Besides, various studies were carried out on biology, genetics, by-catch mitigation, among others, for many of the species under ICCAT mandate. The ICCAT Shark Identification Guide was completed and work was started on the second volume of the Guide.

In 2010, a survey project was continued to determine the possibility of bigeye tuna fishing in Uruguayan waters. This fishing was carried out by Japanese vessels which had $100 \%$ coverage by Uruguayan observers.

## Venezuela

The Venezuelan fleet that fished in the Atlantic targeting pelagic resources was comprised of 69 industrial vessels in 2010: 53 longliners, 8 purse seiners and 8 baitboats. Besides, 35 artisanal vessels were registered that fish using driftnets. This year, landings of tunas and tuna-like species in the Atlantic Ocean amounted to $8,437 \mathrm{t}$. Of these, $98.2 \%$ were tunas, among which the most important species was yellowfin tuna (T. albacares) with $56.7 \%$, while skipjack tuna (K. pelamis), black skipjack (T. atlanticus) and bigeye tuna (T. obesus) catches amounted for $25,1 \%, 3.9 \%$ and $3.4 \%$ of the catch, respectively. The by-catch was comprised of billfishes, notably sailfish (Istiophorus albicans) with $2.1 \%$ and blue marlin (Makaira nigricans) with $1.6 \%$ and sharks whose landings represented $1.7 \%$. The majority of the landings ( $61.2 \%$ ) are from the purse seine fishery, $12.9 \%$ from baitboat, $22.5 \%$ from longline and $3.3 \%$ from the artisanal fisheries. In 2010 research continued on the fishery for large pelagic species, including tunas, billfishes and sharks. The program of scientific observers on board industrial longline vessels continued as did the coverage of the sport fishing tournaments along the central coast of Uruguay.

## - Cooperating Parties, Entities or Fishing Entities

## Chinese Taipei

In 2010, the total number of longline vessels authorized to operate in the Atlantic Ocean was 117, which included 67 vessels authorized to target bigeye tuna and 50 vessels authorized to target albacore. The total catch of tuna and tuna-like species of the longline fleet was estimated to be 31,007 metric tons ( t ) in 2010. Tropical tunas (bigeye tuna, 13189 t and yellowfin tuna, 824 t ) were the most dominant species caught accounting for $45 \%$ of the total catch, and albacore ( $12,562 \mathrm{t}$ ) accounted for $41 \%$. The Fisheries Agency has set catch quotas for Atlantic bigeye tuna, northern and southern Atlantic albacore, and for by-catch species, namely swordfish, blue marlin and white marlin. Catches of these species were well below catch limits allocated by the ICCAT for 2010. All Chinese Taipei longline vessels operating in the Atlantic Ocean were equipped with satellite tracking devices (Vessel Monitoring System, VMS) on board. Statistics (fleets characteristics/Task I/Task II/size/observer bycatch data) were submitted to the ICCAT Secretariat within the required timeframe. In 2010, 18 observers were placed on fishing vessels in the Atlantic Ocean, and the observer coverage was above the requirement set by ICCAT. The research programs for 2010 conducted by scientists included stock assessments, standardizations of catch-per-unit-effort on bigeye tuna, swordfish, albacore and blue marlin (and other incidental catch species), shark fin ratio, shark by-catch re-estimation, incidental catch rate and mortality rate by sighting of seabirds, sea turtles and cetaceans. The research results were presented at the regular meeting and inter-sessional working group meetings of the SCRS.

## 8. Executive Summaries on species

The Committee reiterated that in order to achieve a more rigorous understanding of these Executive Summaries from a scientific point of view, the previous Executive Summaries should be consulted, as well as the corresponding Detailed Reports which are published in the Collective Volume of Scientific Papers.

The Committee also pointed out that the texts and tables of these Summaries generally reflect the information available in ICCAT immediately prior to the SCRS plenary sessions, since they were prepared during the meetings of the Species Groups. Therefore, the catches reported to ICCAT during or after the SCRS meeting cannot be included in these Summaries.

### 8.1 YFT - YELLOWFIN TUNA

A stock assessment for yellowfin tuna was conducted in 2011, at which time catch and effort data through 2010 were available (YFT-Table 1). Readers interested in a more complete summary of the state of knowledge on yellowfin tuna should consult the detailed report of the 2011 ICCAT Stock Assessment of Atlantic Yellowfin Tuna (SCRS/2011/020).

Other information relevant to yellowfin tuna is presented elsewhere in this SCRS Report:

- The Tropical Tunas Work Plan (Appendix 4) includes plans to address research and assessment needs for yellowfin tuna.

## YFT-1. Biology

Yellowfin tuna is a cosmopolitan species distributed mainly in the tropical and subtropical oceanic waters of the three oceans. The sizes exploited range from 30 cm to 170 cm FL; maturity occurs at about 100 cm FL. Smaller fish (juveniles) form mixed schools with skipjack and juvenile bigeye, and are mainly limited to surface waters, while larger fish form schools in surface and sub-surface waters. The main spawning ground is the equatorial zone of the Gulf of Guinea, with spawning primarily occurring from January to April. Juveniles are generally found in coastal waters off Africa. In addition, spawning occurs in the Gulf of Mexico, in the southeastern Caribbean Sea, and off Cape Verde, although the relative importance of these spawning grounds is unknown. Although such separate spawning areas might imply separate stocks or substantial heterogeneity in the distribution of yellowfin tuna, a single stock for the entire Atlantic is assumed as a working hypothesis. This assumption is based upon information such as observed transatlantic movements (from west to east) indicated by conventional tagging and longline catch data that indicates yellowfin are distributed continuously throughout the entire tropical Atlantic Ocean. However, movement rates and timing, routes, and local residence times remain highly uncertain. In addition, some electronic tagging studies in the Atlantic as well as in other oceans suggest that there may be some degree of extended local residence times and/or site fidelity. Natural mortality is assumed to be higher for juveniles than for adults; this is supported by tagging studies for Pacific and Indian Ocean yellowfin. Uncertainties remain as to the scale of these natural mortality rates. Males are predominant in the catches of larger sized fish (over 145 cm ), which could be explained if females experience a higher natural mortality rate (perhaps as a consequence of spawning). On the other hand, females are predominant in the catches of intermediate sizes ( 120 to 135 cm ), which could support a hypothesis of distinct growth curves between males and females, with females having a lower asymptotic size than males. These uncertainties in both natural mortality and growth have important implications for stock assessment.

Growth rates have been described as relatively slow initially, increasing at the time the fish leave the nursery grounds; this characterization is supported by results size frequency distributions as well as from tagging data. Nevertheless, questions remain concerning the most appropriate growth model for Atlantic yellowfin tuna; this discrepancy in growth models could have implications for stock assessments.

The younger age classes of yellowfin tuna exhibit a strong association with FADs (natural or artificial fish aggregating devices/floating objects). The Committee noted that this association with FADs, which increases the vulnerability of these smaller fish to surface fishing gears, may also have a negative impact on the biology and on the ecology of yellowfin due to changes in feeding and migratory behaviors.

## YFT-2. Fishery indicators

Overall Atlantic catches declined by nearly half from the peak catches of $1990(194,000 \mathrm{t})$ to the lowest level in nearly 40 years ( $100,000 \mathrm{t}$ ) in 2007, although catches have increased by about $10 \%$ from that level in recent years (a provisional 108,343 t was estimated for 2010 at the time of the assessment; $107,546 \mathrm{t}$ was reported as of the SCRS Plenary session).

In the eastern Atlantic, purse seine catches declined by $60 \%$ from $128,729 \mathrm{t}$ in 1990 to $50,392 \mathrm{t}$ in 2007, but then increased by about 40\% from that level to 69,953 t in 2010 (YFT-Table 1; YFT-Figure 2). Baitboat catches declined by more than half from 1990 to 2007 (from 19,648 t to $8,896 \mathrm{t}$ ), and have since fluctuated at about that level. Longline catches, which were $10,253 \mathrm{t}$ in 1990, have fluctuated since between $5,790 \mathrm{t}$ and $14,638 \mathrm{t}$ and were $13,437 \mathrm{t}$ in 2007 (a $30 \%$ increase from 1990), but have steadily declined since to a level of 5,834 tin 2010. In the western Atlantic, purse seine catches (predominantly from Venezuela) declined by more than $90 \%$ from a peak in 1994 to 2009 (from 19,612 t to 1,365 t), the lowest level in more than 30 years, before reversing the
trend by increasing to 4,219 t in 2010. Baitboat catches also reached a nearly 30 year low ( 886 t) in 2008, declining nearly $90 \%$ from $7,094 \mathrm{t}$ in 1994, before increasing again to $1,436 \mathrm{t}$ in 2010. Longline catches, which were $11,790 \mathrm{t}$ in 1994, have fluctuated since between $10,059 \mathrm{t}$ and $16,019 \mathrm{t}$, were $12,640 \mathrm{t}$ in 2010.

The most recent available catch distribution is given in YFT-Figure 1. However, it should be noted that official reports are not yet available from several Contracting and/or non-Contracting Parties, and some of these figures are based upon data provided by CPC scientists and/or derived from recent catch levels.

Purse seine catch levels had been held in check until 2007 in large part by a continued decline in the number of purse seine vessels in the eastern Atlantic. As a recent indicator, the number of purse seiners from the European and associated fleet operating in the Atlantic had declined from 44 vessels in 2001 to 25 vessels in 2006, with an average age of about 25 years (see SKJ-Figure 7 for trends in number of vessels and carrying capacity). Since then, however, the number of purse seiners has increased by about $40 \%$ to 35 , as vessels have moved from the Indian Ocean to the Atlantic. At the same time, the efficiencies of these fleets have been increasing, particularly as the vessels which had been operating in the Indian Ocean tend to be newer and with greater fishing power and carrying capacities. Overall carrying capacity of the total purse seine fleet in 2010 has increased to about the same level as in the 1990s and FAD based fishing has accelerated more rapidly than free school fishing (although both have substantially increased), with the number of sets on FADs reaching levels not seen since the mid 1990s.

Unreported purse seine catches were estimated by comparing monitored landings in West African ports and cannery data to catches reported to ICCAT. Estimates of unreported purse seine catches are large and increasing since 2006 and now may exceed $20,000 \mathrm{t}$ for the three main species of tropical tunas. The Committee expressed the need for countries and the involved industry in the region to cooperate to estimate and report these catches correctly to ICCAT. These estimates have not been incorporated into assessments (although the sensitivity of stock status estimates to the inclusion of these catch estimates was evaluated at the 2011 yellowfin tuna stock assessment meeting). These estimates of unreported catch are not included in the total catch estimates presented in this report. The magnitudes of these estimates of unreported catch, however, are likely to influence the assessments and the resulting perception of stock status.

Available catch rate series from purse seine data, after an initial period of apparent declines, showed high variability without clear trend in recent years (YFT-Figure 3). Baitboat catch rate trends (YFT-Figure 4) also exhibit large fluctuations, with a somewhat declining overall trend. Such large fluctuations may reflect changes in local availability and/or fishing power, which do not necessarily reflect stock abundance trends. Standardized catch rates for the longline fisheries (YFT-Figure 5) generally show a declining trend until the mid-1990s, and have fluctuated without clear trend since.

The average weight trends by fleet (1970-2010) are shown in YFT-Figure 6. The recent average weight in European purse seine catches, which represent the majority of the landings, has declined to about half of the average weight of 1990. This decline is at least in part due to changes in selectivity associated with fishing on floating objects beginning in the 1990s. A declining trend is also reflected in the average weight of eastern tropical baitboat catches. Longline mean weights have been more variable.

Apparent changes in selectivity can also be seen in the overall trends in catch at age shown in YFT-Figure 7. The variability in overall catch at age is primarily due to variability in catches of ages 0 and 1 . These ages are generally taken by the surface fisheries around FADs.

## YFT-3. State of the stock

A full stock assessment was conducted for yellowfin tuna in 2011, applying both an age-structured model and a non-equilibrium production model to the available catch data through 2010. As has been done in previous stock assessments, stock status was evaluated using both production and age-structured models. Models used were similar in structure to those used in the previous assessment, however, other alternative model structures of the production model and the VPA were explored in sensitivity runs. These runs confirmed that some of the estimated benchmarks obtained from production models are somewhat sensitive to the assumption used that MSY is obtained at half of the virgin biomass. This assumption was used in the production models that contributed to benchmark estimates found in this report.

The estimate of MSY ( $\sim 144,600 \mathrm{t}$ ) may be below what was achieved in past decades because overall selectivity has shifted to smaller fish (YFT-Figure 7); the impact of this change in selectivity on estimates of MSY is
clearly seen in the results from age structured models (YFT-Figure 8). Bootstrapped estimates of the current status of yellowfin tuna based on each model, which reflect the variability of the point estimates given assumptions about uncertainty in the inputs, are shown in YFT-Figure 9. When the uncertainty around the point estimates from both models is taken into account, there was only an estimated $26 \%$ chance that the stock was not overfished and overfishing was not occurring in 2010 (YFT-Figure 10).

In summary, 2010 catches are estimated to be well below MSY levels, stock biomass is estimated to most likely be about $15 \%$ below the Convention Objective and fishing mortality rates most likely about $13 \%$ below $\mathrm{F}_{\text {MSY }}$. The recent trends through 2010 are uncertain, with the age-structured models indicating increasing fishing mortality rates and decline in stock levels over the last several years, and the production models indicating the opposite trends.

## YFT-4. Outlook

Projections were made considering a number of constant catch scenarios, and the results from all models are summarized to produce estimated probabilities of achieving Convention Objective ( $\mathrm{B}>\mathrm{B}_{\text {MSY }}, \mathrm{F}<\mathrm{F}_{\text {MSY }}$ ), for a given level of constant catch, for each year up to 2025 (YFT-Figure 11 and YFT-Table 2). Maintaining current catch levels ( $110,000 \mathrm{t}$ ) is expected to lead to a biomass somewhat above $\mathrm{B}_{\mathrm{MSY}}$ by 2016 with a $60 \%$ probability. Higher catch levels would have a lower probability of achieving that goal and may require a longer time frame for rebuilding.

The overall catches of yellowfin tuna estimated for 2008-2010 were about $10 \%$ or more higher than the recent low of 2007. The relative contribution of purse seine gear to the total catch has increased by about $20 \%$ since 2006, which is related to the increasing purse seine effort trend. Estimates of fishable biomass trends from production modeling indicate a slow, continued rebuilding tendency, but estimates of spawning stock and total biomass trends from the age-structured assessment indicates recent decline and corresponding increasing F. In either case, continued increasing catches are expected to slow or reverse rebuilding.

## YFT-5. Effects of current regulations

Recommendation 04-01 implemented a closure for the surface fishing in the area $0^{\circ}-5^{\circ} \mathrm{N}, 10^{\circ} \mathrm{W}-20^{\circ} \mathrm{W}$ during November in the Gulf of Guinea. Analyses of purse seine catches which have been presented to the Committee confirmed that the new closure has been less effective than previous moratoria in reducing the proportional catch of small fish harvest and avoiding growth overfishing. If management objectives include reductions in juvenile mortality, there is a general agreement that larger time/area moratoria are likely to be more precautionary than a smaller moratoria, providing that the moratoria are fully complied with.

In 1993, the Commission recommended "that there be no increase in the level of effective fishing effort exerted on Atlantic yellowfin tuna, over the level observed in 1992". As measured by fishing mortality estimates from the age-structured model, effective effort in 2010 appeared to be near (estimates range from about $5 \%$ above to about $10 \%$ below) the 1992 levels.

## YFT-6. Management recommendations

The Atlantic yellowfin tuna stock was estimated to be overfished in 2010. Continuation of current catch levels ( $110,000 \mathrm{t}$ ) is expected to lead to a biomass somewhat above $\mathrm{B}_{\mathrm{MSY}}$ by 2016 with a $60 \%$ probability. Catches approaching $140,000 \mathrm{t}$ or more would reduce the chances of meeting Convention Objectives below $50 \%$, even after 15 years (2025). In addition, the Commission should be aware that increased harvest of yellowfin on FADs could have negative consequences for bigeye tuna in particular, as well as other by-catch species. Should the Commission wish to increase long-term sustainable yield, the Committee continues to recommend that effective measures be found to reduce FAD-related and other fishing mortality of small yellowfin.

If the provisional estimates of unreported purse seine catches are considered, estimates of current stock status and projections would be more pessimistic. It is especially important to implement effective full monitoring of the fleet for which the Committee has provisionally estimated unreported catch.

## ATLANTIC YELLOWFIN TUNA SUMMARY

Maximum Sustainable Yield (MSY)
2010 Yield $^{2}$
Relative Biomass $\quad \mathrm{B}_{2010} / \mathrm{B}_{\mathrm{MSY}}$
Relative Fishing Mortality: $\mathrm{F}_{\text {current(2010) }} / \mathrm{F}_{\text {MSY }}$
Management measures in effect:

- Effective fishing effort not to exceed 1992 level [Rec. 93-04].

NOTE: $\mathrm{F}_{\text {current(2010) }}$ refers to $\mathrm{F}_{2010}$ in the case of ASPIC, and the geometric mean of F across 2007-2010 in the case of VPA. As a result of the constant trend in recruitment estimated by the VPA model, $\mathrm{F}_{\text {MAX }}$ is used as a proxy for $\mathrm{F}_{\text {MSY }}$ for VPA results. Relative biomass is calculated in terms of spawning stock biomass in the case of VPA and in fishable biomass in the case of ASPIC.
${ }^{1}$ Estimates (with $80 \%$ confidence limits) based upon results of both the non-equilibrium production model (ASPIC) and the agestructured model (VPA).
${ }^{2}$ Reported as of the SCRS Plenary session. The assessment was conducted using the available catch data through 2010. A provisional $108,343 t$ was estimated for 2010 at the time of the assessment.
${ }^{3}$ Median ( $10^{\text {th }}-90^{\text {th }}$ percentiles) from joint distribution of age-structured and production model bootstrap outcomes considered.

YFT-Table 1. Estimated catches (t) of yellowfin tuna (Thunnus albacares) by area, gear and flag.

* Current Task I figures (2009 and 2010) where the shaded cells indicate which catches have changed since the assessment.

YFT-Table 2. Kobe II matrices giving the probability that the biomass will exceed the level that will produce MSY and the fishing mortality will fall below the fishing mortality rate that would maintain MSY, in any given year, for various constant catch levels based on combined model results.

|  | Probability (\%) that $B>B_{M S Y}$ and $F<F_{M S Y}$ in each year |  |  |  |  |  |  |  |  |  |  |  |  |  |

YFT-Figure 11. Probability plot based on Kobe II matrices giving the probability that the biomass will exceed the level that will produce MSY and the fishing mortality will fall below the fishing mortality rate that would maintain MSY, in any given year, for various constant catch levels based on combined model results.

### 8.2 BET-BIGEYE TUNA

The last stock assessment for bigeye tuna was conducted in 2010 through a process that included a data preparatory meeting in April (Anon. 2011a) and an assessment meeting in July (Anon. 2011b). The last year fishery data used was 2009 but most indices of relative abundance stopped in 2008.

## BET-1. Biology

Bigeye tuna are distributed throughout the Atlantic Ocean between $50^{\circ} \mathrm{N}$ and $45^{\circ} \mathrm{S}$, but not in the Mediterranean Sea. This species swims at deeper depths than other tropical tuna species and exhibits extensive vertical movements. Similar to the results obtained in other oceans, pop-up tagging and sonic tracking studies conducted on adult fish in the Atlantic have revealed that they exhibit clear diurnal patterns: they are found much deeper during the daytime than at night. In the eastern tropical Pacific, this diurnal pattern is exhibited equally by juveniles and adults. Spawning takes place in tropical waters when the environment is favorable. From nursery areas in tropical waters, juvenile fish tend to diffuse into temperate waters as they grow larger. Catch information from surface gears indicate that the Gulf of Guinea is a major nursery ground for this species. Dietary habits of bigeye tuna are varied and prey organisms like fish, mollusks, and crustaceans are found in their stomach contents. Bigeye tuna exhibit relatively fast growth: about 105 cm fork length at age three, 140 cm at age five and 163 cm at age seven. Bigeye tuna over 200 cm are relatively rare. Bigeye tuna become mature after they reach 100 cm at between 3 and 4 years old. Young fish form schools mostly mixed with other tunas such as yellowfin tuna and skipjack. These schools are often associated with drifting objects, whale sharks and sea mounts. This association appears to weaken as bigeye tuna grow larger. Estimated natural mortality rates for juvenile fish, obtained from tagging data, were of a similar range as those applied in other oceans. Various pieces of evidence, such as a lack of identified genetic heterogeneity, the time-area distribution of fish and movements of tagged fish, suggest an Atlantic-wide single stock for this species, which is currently accepted by the Committee. However, the possibility of other scenarios, such as north and south stocks, should not be disregarded.

## BET-2. Fisheries indicators

The stock has been exploited by three major gears (longline, baitboat and purse seine fisheries) and by many countries throughout its range of distribution and ICCAT has detailed data on the fishery for this stock since the 1950s. Scientific sampling at landing ports for purse seine vessels of the EU and associated fleets have been conducted since 1980 to estimate bigeye tuna catches (BET-Figure 1, BET-Table 1). The size of fish caught varies among fisheries: medium to large for the longline fishery, small to large for the directed baitboat fishery, and small for other baitboat and for purse seine fisheries.

The major baitboat fisheries are located in Ghana, Senegal, the Canary Islands, Madeira and the Azores. The tropical purse seine fleets operate in the Gulf of Guinea in the East Atlantic and off Venezuela in the West Atlantic. In the eastern Atlantic, these fleets are comprised of vessels flying flags of Ghana, EU-France, EUSpain and others which are mostly managed by EC companies. In the western Atlantic the Venezuelan fleet dominates the purse-seine catch of bigeye tuna. While bigeye tuna is now a primary target species for most of the longline and some baitboat fisheries, this species has always been of secondary importance for the other surface fisheries. In the surface fishery, unlike yellowfin tuna, bigeye tuna are mostly caught while fishing on floating objects such as logs or man-made fish aggregating devices (FADs). During 2009, landings in weight of bigeye tuna caught by the longline fleets of Japan and Chinese Taipei, and the purse seine and baitboat fleets of the EU and Ghana represented $75 \%$ of the total bigeye tuna catch.

The total annual Task I catch (BET-Table 1, BET-Figure 2) increased up to the mid-1970s reaching 60,000 t and fluctuated over the next 15 years. In 1991, catch surpassed $95,000 \mathrm{t}$ and continued to increase, reaching a historic high of about $133,000 \mathrm{t}$ in 1994. Reported and estimated catch has been declining since then and fell below $100,000 \mathrm{t}$ in 2001. This gradual decline in catch has continued, although with some fluctuations from year to year. The preliminary estimate for 2010 is 75,833t.

After the historic high catch in 1994, all major fisheries exhibited a decline of catch while the relative share by each fishery in total catch remained relatively constant. These reductions in catch are related to declines in fishing fleet size (longline) as well as decline in CPUE (longline and baitboat). The number of active purse seiners declined by more than half from 1994 until 2006, but then increased since 2007 as some vessels returned from the Indian Ocean to the Atlantic. The number of purse seiners operating in 2009 and 2010 was similar to the number operating in 2003-04 (SKJ-Figure 6).

IUU longline catches were estimated from Japanese import statistics but the estimates are considered uncertain. These estimates indicate a peak in unreported catches of $25,000 \mathrm{t}$ in 1998 and a quick reduction thereafter. The Committee expressed concern that historical catches from illegal, unreported and unregulated (IUU) longliners that fly flags of convenience from the Atlantic might have been poorly estimated. The magnitude of this problem has not yet been quantified, because available statistical data collection mechanisms are insufficient to provide alternative means to calculate unreported catch.

Unreported purse seine catches were estimated by comparing monitored landings in West African ports and cannery data to catches reported to ICCAT. Estimates of unreported purse seine catches are larger and increasing since 2006 and now may exceed 20,000 tons for the three main species of tropical tunas. The Committee expressed the need for countries and the involved industry in the region to cooperate to estimate and report these catches correctly to ICCAT. These estimates have not been incorporated into assessments and are not included in the catch estimates presented in this report. The magnitudes of these estimates of IUU catch, however, are likely to influence the assessments and the resulting perception of stock status.

Significant catches of small bigeye tuna continue to be channeled to local West African markets, predominantly in Abidjan, and sold as "faux poissons" in ways that make their monitoring and official reporting challenging. Monitoring of such catches has progressed in some countries but there is still a need for a coordinated approach that will allow ICCAT to properly account for these catches and thus increase the quality of the basic catch data available for assessments.

Mean average weight of bigeye tuna decreased prior to 1998 but has been relative stable, at around 10 kg during the last decade (BET-Figure 3). This weight, however, is quite different according to the fishing gear, around 62 kg for longliners, 7 kg for bait boats, and 4 kg for purse seiners. In the last ten years all longline fleets have shown increases in mean weight of bigeye tuna caught, with the average longline-caught fish increasing from 40 kg to 60 kg between 1999 and 2010. During the same period purse seine-caught bigeye tuna had weights between 3 kg and 4 kg . Bigeye tuna caught in free schools are more than two times heavier than those caught around FADs. This difference in weight between these two fishing modes is even more pronounced since 2006. Since FAD catches began being identified separately in 1991 by EU and associated purse seine fleets, the majority ( $75 \%-80 \%$ ) of bigeye tuna are caught in sets associated with FADs. Similarly baitboat-caught bigeye tuna weighted between 6 and 10 kg over the same period, showing greater inter-annual variability in fish weight than longline or purse seine caught fish.

## BET-3. State of the stock

The 2010 stock assessment was conducted using similar assessment models to those used in 2007 (Anon. 2008) but with updated data and a few new relative abundance indices and data. In general, data availability has continued to improve, notably with the addition of relative abundance indices for an increasing number of fleets. There are still missing data on detailed fishing and fish size from certain fleets. In addition, there are a number of data gaps on the activities of IUU fleets (e.g., size, location and total catch). All these problems forced the committee to assume catch-at-size for an important part of the overall catch.

Three types of indices of abundance were used in the assessment. A number of indices were directly developed by national scientists for selected fleets for which data was available at greater spatial and or temporal resolution to that available in the ICCAT databases. These indices represented data for seven different fleets, all of them longline fleets, except for one baitboat fleet (BET-Figure 4). Other indices were estimated by the committee from data available within the ICCAT databases. These two types of indices were used for age-structured assessment models. Finally, a series of combined indices (BET-Figure 5) were calculated by the committee by synthesizing the information existing in individual indices for the seven fleets mentioned above. The later were used to fit production models.

Consistent with previous assessments of Atlantic bigeye tuna, the results from non-equilibrium production models are used to provide the basic characterization of the status of the resource. Results were sensitive to the combined abundance index trends assumed. As the relative likelihoods of each trend could not be estimated, results were developed from the joint distribution of model run results using each of three alternative combined indices. The plausible range of MSY estimated from the joint distribution using three types of abundance indices was between 78,700 and 101,600 tons ( $80 \%$ confidence limits) with a median MSY of $92,000 \mathrm{t}$. In addition, these estimates reflect the current relative mixture of fisheries that capture small or large bigeye tuna; MSY can change considerably with changes in the relative fishing effort exerted by surface and longline fisheries. Historical estimates show large declines in biomass and increases in fishing mortality, especially in the mid

1990s when fishing mortality exceeded $\mathrm{F}_{\text {MSY }}$ for several years. In the last five or six years there have been possible increases in biomass and declines in fishing mortality (BET-Figure 6). The biomass at the beginning of 2010 was estimated to be at between 0.72 and 1.34 ( $80 \%$ confidence limits) of the biomass at MSY, with a median value of 1.01 and the 2009 fishing mortality rate was estimated to be between $0.65-1.55$ ( $80 \%$ confidence limits) with a median of 0.95 . The replacement yield for the year 2011 was estimated to be about MSY.

The Committee notes, as it did in previous assessments, that there is considerable uncertainty in the assessment of stock status and productivity for bigeye tuna. There are many sources of uncertainty including which method represents best the dynamics of the stock, which method is supported more by the available data, which relative abundance indices are appropriate to be used in the assessment, and what precision is associated with the measurement/calculation of each of the model inputs. In general, data availability has improved since 2007 but there is still a lack of information regarding detailed fishing effort and catch-at-size data from certain fleets. This, combined with the lack of detailed historical information on catch and fishing activities of IUU fleets (e.g., size, location and total catch), forces the Committee to make many assumptions about the catch-at-size for an important part of the overall catch. In order to represent this uncertainty the Committee decided to combine sensitivity runs from a range of method/data combinations. There are differences in the estimates of management benchmarks, including the estimates of the current biomass and fishing mortality, depending on both the method used as well as the input data used (BET-Figure 7).

## BET-4. Outlook

The outlook for Atlantic bigeye tuna, considering the quantified uncertainty in the 2010 assessment, is presented in BET-Table 2 and BET-Figure 8, which provide a characterization of the prospects of the stock achieving or being maintained at levels consistent with the Convention Objective, over time, for different levels of future constant catch. It is noteworthy that the modeled probabilities of the stock being maintained at levels consistent with the Convention Objective over the next five years are about $60 \%$ for a future constant catch of $85,000 \mathrm{t}$. Higher odds of rebuilding to and maintaining the stock at levels that could produce MSY are associated with lower catches and lower odds of success with higher catches than such constant catch (BET-Figure 9). It needs to be noted that projections made by the Committee assume that future constant catches represent the total removals from the stock, and not just the TAC of 85,000 t established by ICCAT [Rec. 09-01]. Catches made by other fleets not affected by [Rec. 09-01] need to be added to the $85,000 \mathrm{t}$ for comparisons with the future constant catch scenarios contemplated in BET-Table 2. Furthermore, any future changes in selectivity due to changes in the ratios of relative mortality exerted by the different fleets - such as an increase in the relative mortality of small fish - will change and add to the uncertainty of these projections.

## BET-5. Effects of current regulations

During the period 2005-2008 an overall TAC for major countries was set at 90,000 t . The TAC was later lowered [Rec. 09-01] to 85,000 t. Estimates of catch for 2005-2010 (BET-Table 1) seem to have been always lower than the corresponding TAC.

Concern over the catch of small bigeye tuna partially led to the establishment of spatial closures to surface fishing gear in the Gulf of Guinea [Recs. 04-01 and 08-01] The Committee examined trends in average bigeye tuna weight as a broad indicator of the effects of such closures. Although there have been significant changes in the average size of bigeye tuna caught since 2004 by certain fleets, such as increases in average size of fish caught by purse seiners operating in free schools and by longliners, it cannot be quantified whether changes are the result of spatial closures. The Committee also analyzed the ICCAT conventional tag database for evidence of an effect of spatial closures. Again, this analysis failed to provide any conclusive evidence in support of the hypothesis that spatial closures led to a reduction in the fishing mortality of juvenile bigeye tuna.

## BET-6. Management recommendations

Projections indicate that catches reaching $85,000 \mathrm{t}$ or less will promote stock growth and further reduce the future chances that the stock will not be at a level that is consistent with the convention objectives. The Commission should be aware that if major countries were to take the entire catch limit set under Recommendations 04-01 and 09-01 and other countries were to maintain recent catch levels, then the total catch could well exceed $100,000 \mathrm{t}$. The Committee recommends that the Commission sets a TAC at a level that would provide a high probability of maintaining at or rebuilding to stock levels consistent with the Convention
objectives. In considering the uncertainty in assessment results, the Committee believes that a future total catch of $85,000 \mathrm{t}$ or less would provide such high probability.

The assessment and subsequent management recommendations are conditional on the reported and estimated history of catch for bigeye tuna in the Atlantic. The Committee reiterates its concern that unreported catches, including those part of the "faux poisson" category, from the Atlantic might have been poorly estimated. There is a need to expand current statistical data collection mechanisms to fully investigate any evidence of significant catches that have been unreported.

|  | ATLANTIC BIGEYE TUNA SUMMARY |
| :--- | :---: |
| Maximum Sustainable Yield | $78,700-101,600 \mathrm{t}(\text { median } 92,000 \mathrm{t})^{1,2}$ |
| Current (2010) Yield ${ }^{1}$ | $75,833 \mathrm{t}^{3}$ |
| Replacement Yield (2011) | $64,900-94,000$ (median $86,000 \mathrm{t}$ ) ${ }^{1,2}$ |
| Relative Biomass ( $\mathrm{B}_{2009} / \mathrm{B}_{\mathrm{MSY}}$ ) | $0.72-1.34(\text { median } 1.01)^{1,2}$ |
| Relative Fishing Mortality |  |
| $\mathrm{F}_{2009} / \mathrm{F}_{\mathrm{MSY}}$ | $0.65-1.55$ (median 0.95$)^{1,2}$ |

Conservation \& management measures in effect:
[Rec. 09-01], para. 1 of [Rec. 06-01], [Rec. 04-01], and [Rec. 10-01].

- Total allowable catch for 2010 is set at $85,000 \mathrm{t}$ for Contracting Parties and Cooperating non-Contracting Parties, Entities or Fishing Entities.
- Limits on numbers of fishing vessels less than the average of 1991 and 1992.
- Specific limits of number of longline boats; China (45), Chinese Taipei (75), Philippines (10), and Korea (16).
- Specific limits of number of purse seine boats; Panama (3).
- No purse seine and baitboat fishing during November in the area encompassed by $0^{\circ}-5^{\circ} \mathrm{N}$ and $10^{\circ} \mathrm{W}-20^{\circ} \mathrm{W}$.

F/FMSY

BET-Figure 6. Trajectories of $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\text {MSY }}$ estimated from the logistic production model. Lines represent the $80 \%$ percentile of bootstrap results and thicker line the median.

BET-Figure 7. Kobe plot from combined examinations of assessment models. Shaded lines shown represent the $80 \%$ confidence limits for the historical trajectory (1950-2009) and solid line represents the median estimated from the logistic production model. Points depict uncertainty in current status not considered by the bootstrapping of the logistic production model (estimates of $\mathrm{F}_{2009} / \mathrm{F}_{\mathrm{MSY}}$ and $\mathrm{B}_{2009} / \mathrm{B}_{\mathrm{MSY}}$ for each of the sensitivity trials from the other models considered in the assessment).

BET-Figure 8. Biomass projections ( $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ ) for bigeye tuna for 2011-2021. Each panel corresponds to a different level of future constant catch from 60,000 to 110,000 tons. Thick lines represent median of all combined runs and thinner lines the 10 and 90 percentiles.

BET-Figure 9. Kobe matrix plot showing probabilities of the stock being above $\mathrm{B}_{\text {MSy }}$ and fishing at levels below $\mathrm{F}_{\text {MSY }}$ in a given year for a future constant catch (TAC). Projections were calculated from results of the combination of the three logistic production model runs used as the basis of the assessment. The colors represent modeled probabilities: red, $<50 \%$, yellow, $50-75 \%$ and green, $>75 \%$. The $60 \%$ probability isopleth is also shown as a black line.

### 8.3 SKJ - SKIPJACK TUNA

Stock assessments for eastern and western Atlantic skipjack were conducted in 2008 (Anon. 2009a) using available catches to 2006. Skipjack had only been assessed previously in 1998 (Anon. 1999). Consequently, this report includes the most recent information on the state of the stocks on this species.

## SKJ-1. Biology

Skipjack tuna is a gregarious species that is found in schools in the tropical and subtropical waters of the three oceans (SKJ-Figure 1). Skipjack is the predominant species under FADs where it is caught in association with juvenile yellowfin tuna, bigeye tuna and with other species of epipelagic fauna. One of the characteristics of skipjack is that from the age of one it spawns opportunistically throughout the year and in vast sectors of the ocean. A recent analysis of tagging data from the eastern Atlantic confirmed that the growth of skipjack varies according to the latitude. However, this difference in the growth rate is not as great as that which had been previously estimated.

The increasing use of fish aggregation devices (FADs) since the early 1990s, have changed the species composition of free swimming schools. It is noted that, in effect, the free schools of mixed species were considerably more common prior to the introduction of FADs. Furthermore, the association with FADs may also have an impact on the biology (food intake, growth rate, plumpness of the fish) and on the ecology (displacement rate, movement orientation) of skipjack and yellowfin (ecological trap concept).

## SKJ-2. Fisheries indicators

The total catches obtained in 2010 in the entire Atlantic Ocean (including estimates of skipjack in the fauxpoisson landed in Côte d'Ivoire by the EU-purse seiners) were at least $183,000 \mathrm{t}$ and could reach around 190 to $195,000 \mathrm{t}$, if the update of catches for Brazil in 2010 confirms the catch average of those taken in recent years (SKJ-Table 1, SKJ-Figure 2) which represents a great increase compared to the catch average of the last five years. It is possible however, that the catches of a segment of the Ghanaian purse seine fleet, transshipped at sea on carriers, skip the collection process of fishery statistics.

The numerous changes that have occurred in the skipjack fishery since the early 1990s (such as the progressive use of FADs and the increase of the fishing area towards the west) have brought about an increase in skipjack catchability and in the biomass proportion that is exploited. At present, the major fisheries are the purse seine fisheries, particularly those of EU-Spain, Ghana, Panama, EU-France and Curaçao, followed by the baitboat fisheries of Ghana, EU-Spain, EU-Portugal and EU-France. The preliminary estimates of catches made in 2010 in the East Atlantic amounted to $164,000 \mathrm{t}$, that is, an increase of around $35 \%$ compared to the average of 20052009 (SKJ-Figure 3). In recent years, the seasonal fishing by European purse seiners on free schools, off Senegal, has decreased sharply (SKJ-Figure 1) and consequently, the proportion of the catches on floating objects has continued to increase, reaching slightly more than $90 \%$ of the catches (SKJ-Figure 4).

The unreported catches of some purse seine catches were estimated by comparing monitored landings in West African ports and cannery data to catches reported to ICCAT. Estimates of the unreported catches of these purse seine catches are larger and increasing since 2006 and now may exceed 20,000 tons for the three main species of tropical tunas. The committee expressed the need for countries and the involved industry in the region to cooperate to estimate and report these catches correctly to ICCAT. These estimates have not been incorporated into assessments and are not included in the catch estimates presented in this report. The magnitudes of these estimates of IUU catch, however, are likely to influence the assessments and the resulting perception of stock status.

The estimate of the average discard rate of skipjack tuna under FADs from data collected since 2001 by observers on-board Spanish purse seiners operating in the East Atlantic has been confirmed by the two new studies conducted on board French purse seiners (estimated at 42 kg per ton of skipjack landed). Furthermore, this last study showed that the amount of small skipjack (average size 37 cm FL ) landed in the local market of Abidjan in Côte d'Ivoire as faux-poisson is estimated at 235 kg per ton of skipjack landed (i.e. an average of 6,641 t/year between 1988 and 2007 for the European or associated purse seiners, SKJ-Figure 5). However, new estimates, on the specific composition in particular, of faux-poisson, carried out during the recent Tropical Tuna Species Group Inter-sessional Meeting on the Ghanaian Statistics Analysis, indicate amounts of around 11,000 t/year between 2005 and 2010 for the overall purse seiners operating in the East Atlantic (3,919 t/year for the European purse seiners) .The Committee regularly integrates these estimates in the reported historical catches for the EU-purse seiners since 1981, as well as in the catch-at-size matrix.

In the West Atlantic, the major fishery is the Brazilian baitboat fishery, followed by the Venezuelan purse seine fleet. Preliminary estimates of catches in 2010 in the West Atlantic amounted to $18,000 \mathrm{t}$, but the complete submission of Brazil's Task I data should bring this amount towards the average catch observed for recent years (SKJ-Figure 6).

It is difficult to estimate effective fishing effort for skipjack tuna in the East Atlantic. Nominal purse seine effort, expressed in terms of carrying capacity, has decreased regularly since the mid-1990s up to 2006. However, due to acts of piracy in the Indian Ocean, many European Union purse seiners have transferred their effort to the East Atlantic. This new situation, which added to the presence of one new purse seine fleet operating from Tema (Ghana), and whereby catches are probably highly underestimated, has considerably increased the carrying capacity of this fishing gear (SKJ-Figure 7). The number of EU purse seiners in the East Atlantic follows this trend but seems to have stabilized in 2010, according to the preliminary estimates. On the other hand, baitboat nominal effort has remained stable for more than 20 years.

It is considered that the increase in fishing power linked to the introduction of innovation technologies on board the vessels as well as to the development of fishing under floating objects has resulted in an increase in the efficiency of the various fleets, since the early 1980s. In addition to the use of an average $3 \%$ annual increase in skipjack catchability to account for these changes, a new analysis has been conducted by fixing MSY and K at levels that agree with estimates made during previous stock assessments. This method provides a range of increase in catchability from 1 to $13 \%$ per year. It is unclear, however, whether these estimates reflect technological changes only, or also in the availability of the fish (e.g., resulting from an expansion of the surface exploited over the years; SKJ-Figure 8). The recent increase in the area explored successfully which corresponds to the extension of the fishery towards the central West Atlantic and off Angola should also be noted.

The significant increase in the estimates of total mortality ( $Z$ ) between the early 1980s and the end of the 1990s obtained from different methods, such as the tag-recovery model, the catch curves by size and the average size observed in the yearly catches, supports this hypothesis. The change in the selectivity pattern observed for the purse seine fishery suggests that this fleet is mainly targeting juvenile tunas. The comparison of the size distributions of skipjack for the East Atlantic between the periods prior to, and following the use of FADs, also reinforces this interpretation insofar as an increase is observed in the proportion of small fish in the catches, as shown by the change of the average weight over the years (SKJ-Figure 9). Generally, it is noted that the average weight observed in the east Atlantic (close to 2 kg ) is much lower than the estimates given in the other oceans (closer to 3 kg ).

The regular increase in fishing pressure observed for the other indicators is confirmed up to about 1995, then the decline in apparent Z (a trend also observed for yellowfin) could be a consequence of the moratoria on floating objects which has mainly affected skipjack (SKJ-Figure 10).

With respect to the West Atlantic, the fishing effort of the Brazilian baitboats (i.e., the major skipjack fishery in this region) seems to be stable over the last 20 years.

## SKJ-3. State of the stocks

In all the oceans and consequently in all the tuna RFMOs, the traditional stock assessment models have been difficult to apply to skipjack because of their particular biological and fishery characteristics (on the one hand, continuous spawning, areal variation in growth and non-directed effort, and on the other, weak identified cohorts). In order to overcome these difficulties, several different assessment methods which accommodate expert opinion and prior knowledge of the fishery and biological characteristics of skipjack have been carried out on the two stocks of Atlantic skipjack. Several fishery indictors were also analyzed to carry out a follow up of the development in the state of the stock over time.

Although the fisheries operating in the east have extended towards the west beyond $30^{\circ} \mathrm{W}$ longitude, the Committee decided to maintain the hypothesis in favor of two distinct stock units, based on available scientific studies. However, taking into account the state of current knowledge of skipjack tuna migrations and the geographic distances between the various fishing areas (SKJ-Figure 1 and SKJ-Figure 11), the use of smaller stock units continues to be the envisaged working hypothesis.

## Eastern stock

The Committee analyzed two standardized indices from the EU-purse seine fishery: An index accounts for skipjack caught in free school in the Senegalese area during the second quarter of the year and the second index characterizing small fish captured under FADs in the equatorial area (SKJ-Figure 12). In previous meetings of the Tropical Tunas Species Group it was confirmed that the increase in CPUE of the European purse seiners in the late 1990s was due, mainly, to the increase in the catches of positive sets under FADS (SKJ-Figure 13). Furthermore, the regular increase in the skipjack yields of the baitboats based in Senegal may only have been the result of an increase in catchability linked to the adoption of the so-called "baitboat associated school" fishing towards the mid-1980s (SKJ Figure 14) and/or to seasonal changes of fishing zones as suggested by a recent study on this fishery. Furthermore, no marked trend has been observed for the Canary Islands baitboats as well as for a peripheral fishery such as the Azorean baitboat fishery. The fact that a reduction in abundance for a local segment of the stock would have little repercussion on abundance in other areas, leads to suppose that only a minor proportion of skipjack carry out extensive migrations between areas (SKJ-Figure 11; cf. notion of stock viscosity). This assumption was reinforced by a recent tagging study on growth variability of skipjack between two eastern Atlantic regions divided by $10^{\circ} \mathrm{N}$ latitude, which were established on the basis of their low amount of mixing (only $0.9 \%$ of the tagged fish crossed this latitudinal limit).

A new Bayesian method, using only catch information (under a Schaefer-type model parameterization), estimated the MSY at $143,000-156,000 \mathrm{t}$, a result which agrees with the estimate obtained by the modified Grainger and Garcia approach: 149,000 t.

In addition, two non-equilibrium surplus biomass production models (a multi-fleets model and a Schaefer-based model) were applied for 8 time series of CPUEs, and for a combined CPUE index weighted by fishing areas. To account for the average increase in catchability of purse seine fisheries, a correction factor of $3 \%$ per year was applied to the CPUE series. As for the Bayesian model application that only uses catches, different working hypothesis were tested on the distribution of the priors of the two surplus production models (i.e., the growth rate, the carrying capacity, the catchability coefficient of each fleet, etc.). In general, the range of plausible MSY values estimated from these models (155,000-170,000 t) were larger than in the bayesian model based on catches. The Committee stated the difficulty to estimate MSY under the continuous increasing conditions of the exploitation plot of this fishery (one-way of the trajectory to substantially weaker effort values) and which as a result, the potential range distribution of some priors needs to be constrained (e.g., for growth rate, or for the shape parameter of the generalized model).

While caution is needed as regards to the generalization of the diagnosis on the stock status of the overall spatial components of this stock in the East Atlantic, due to the moderate mixing rates that seem to occur among the different sectors of this region, it is unlikely that skipjack be exploited in the eastern Atlantic (SKJ-Figure 15).

## Western stock

The standardized CPUEs of Brazilian baitboats remain stable while that of Venezuelan purse seiners and USA rod and reel decreased in recent years (SKJ-Figure 16). This decrease, also observed in the CPUE time series for Venezuelan purse seine, could be linked to specific environmental conditions (high surface temperatures, lesser accessibility of prey). The average weight of skipjack caught in the western Atlantic is higher than in the east ( 3 to 4.5 kg vs. 2 to 2.5 kg ), at least for the Brazilian baitboat fishery.

The assessment model from catches estimated MSY at around $30,000 \mathrm{t}$ (similar to the estimate provided by the Grainger and Garcia approach) and the Bayesian surplus model (Schaefer formulation) at 34,000 t.

The Group attempted several sensitivity analyses for values of natural mortality with Multifan-CL. For this stock only the three fisheries mentioned above were considered. The final estimate of MSY converges also at about: 31,000-36,000 t . It must be stressed that all of these analyses correspond to the current geographic coverage of this fishery (i.e., relatively coastal fishing grounds due to the deepening of the thermocline and of the oxycline to the East).

For the western Atlantic stock, in the light of the information provided by the trajectories of $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$, it is unlikely that the current catch is larger than the current replacement yield (SKJ-Figure 17).

## SKJ-4. Effects of current regulations

There is currently no specific regulation in effect for skipjack tuna.

However, with the aim of protecting juvenile bigeye tuna, the French and the Spanish boat owners voluntarily decided to apply a moratorium for fishing under floating objects between November and the end of January for the 1997-1998 and 1998-1999 periods. The Commission implemented a similar moratorium from 1999 to January 2005. This moratorium has had an effect on skipjack catches made with FADs.

On the basis of a comparison of average catches between 1993-1996, prior to the moratoria, and those between the 1998-2002 period, the average skipjack catches between November and January for the purse seine fleets that applied the moratoria, were reduced by $64 \%$. During that period (1998-2002), the average annual skipjack catches by purse seine fleets that applied the moratoria decreased by $41 \%$ ( $42,000 \mathrm{t}$ per year). However, this decrease is possibly a combined result of the decrease in effort and the impact of the moratoria (the average annual catch per boat decreased only $18 \%$ between these two periods).

The repealing in 2006 of Recommendation [Rec. 05-01] on the 3.2 kg minimum size limit on yellowfin tuna [Rec. 72-01] (although it remained in force in 2005) and the establishment of a time/area closure of the surface fishery [Rec. 04-01], which replaces the old strata relative to the moratorium on catches under floating objects, are regulatory measures whose effects were analyzed during the Species Group meeting.

Considering that the new closed area is much smaller in time and surface than the previous moratorium time/area, and is located in an area which historically has lower effort anyway, this regulation is likely to be less effective in reducing the overall catches of small bigeye (the species for which the regulation was applied) by the surface fishery. When the fishing effort for the EU purse seine fleet was at its maximum value (period 19941996, i.e., before the implementation of the first moratorium), the skipjack catch from this fleet within the time and area limits defined by Rec. 04-01, was only on average at $7,180 \mathrm{t}$ (i.e., $7.5 \%$ of the total skipjack catch from the EU purse seiners).

## SKJ-5. Management recommendations

Although the Committee makes no management recommendations in this respect, catches should not be allowed to exceed MSY. The Commission should be aware that increasing harvests and fishing effort for skipjack could lead to involuntary consequences for other species that are harvested in combination with skipjack in certain fisheries.

## ATLANTIC SKIPJACK TUNA SUMMARY

|  | East Atlantic | West Atlantic |
| :--- | :--- | :--- |
| Maximum Sustainable Yield (MSY) | Around 143,000-170,000 t | Around 30,000-36,000 t |
| Current (2010) Yield ${ }^{1}$ | $164,000 \mathrm{t}$ | $18,000 \mathrm{t}$ |
| Current Replacement Yield | Somewhat higher than 164,000 t | Somewhat higher than 18,000 t |
| Relative Biomass $\left(\mathrm{B}_{2008} / \mathrm{B}_{\mathrm{MSY}}\right)$ | Most likely $>1$ | Most likely $>1$ |
| Relative Fishing Mortality: $\left(\mathrm{F}_{2008} / \mathrm{F}_{\mathrm{MSY}}\right)$ | Most likely<1 | Most likely<1 |
| Management measures in effect | Rec. 04-01 (effective 2005) ${ }^{2}$ | None |

SKJ-Figure 1. (A) Distribution of skipjack catches in the Atlantic for baitboat between 1960 and 2009 (upper left panel) and for purse seiners by fishing mode (free schools vs FADs) between 1991 and 2009. (B) Skipjack catches made by European purse seiners (about 75\% of the total catches) 1996-2005 (lower left panel) and 20062009 (lower right panel) showing the withdrawal from the Senegal zone due to non-renewal of the fishing agreements.

SKJ-Figure 2. Total catch (t) for skipjack tuna in the Atlantic Ocean and by stocks (East and West) between 1950 and 2010. Estimates of skipjack in the "faux poissons" landed in Côte d'Ivoire were included in the skipjack trade catches in the eastern Atlantic (only catches to 2006 were considered for the stock assessment). The estimate of total catches in the West Atlantic (and consequently for all the Atlantic), remains preliminary. It is also possible that skipjack catches taken in the eastern Atlantic during recent years were not reported.

SKJ-Figure 3. Skipjack catches in the eastern Atlantic, by gear (1950-2010). It is possible that skipjack catches taken by purse seiners in the eastern Atlantic during recent years were not reported.

SKJ-Figure 4. Changes in the proportion of skipjack catches made by European purse seiners under FADs (1991-2010). ). The increase in the percentage of catches under FADs coincides with the shift from the Senegal area (due to not renewing the fishing agreements); Area known for its seasonal fishing on free schools (see Figure 1).

SKJ-Figure 5. Cumulative estimated landings of "faux poissons" (1981-2010) for the European or associated purse seiners for the three main species of tropical tunas in the local market of Abidjan (Côte d'Ivoire).

SKJ-Figure 6. Skipjack catches in the western Atlantic, by gear (1950-2010). The estimate for 2010 for baitboat is still preliminary.

SKJ-Figure 7. Changes over time in the carrying capacity, corrected by time at sea, (left axis) for the overall purse seiners and baitboats operating in the eastern Atlantic (1971-2010) and in number of boats for the European purse seiners (right axis). It is possible that the carrying capacity for some segments of the purse seine fleet was underestimated during recent years.

SKJ-Figure 8. Number of $1^{\circ} \times 1^{\circ}$ squares with catch of skipjack for the purse seiners operating in the eastern Atlantic (1969-2010). The increase observed in 1991 could be due to a modification of the species composition correction procedure of the catches implemented at this date (skipjack catches could have been attributed to squares which were not included until then). On the other hand, the recent increase in the area searched successfully corresponds to the extension of the fishery towards the western central Atlantic and off Angola.

SKJ-Figure 9. Changes in time of the mean weight of the skipjack landed (non standardized) by major fisheries in the eastern Atlantic.

SKJ-Figure 10. Changes over time in the apparent total mortality Z, calculated based on Beverton and Holt's equation, for the three main tropical tuna species in the Atlantic Ocean. YFT = yellowfin, BET = bigeye, SKJ = Eastern skipjack. The size at which the fish are fully recruited was fixed at 50 cm (FL).

SKJ-Figure 11. Distribution of tagged and released SKJ (left panel) and apparent movements from geographic positions of recaptured fish (right panel).

SKJ-Figure 12. Standardized skipjack CPUE for EU purse seiners in the eastern Atlantic Ocean. Free = free school off Senegal; FAD = schools associated with fish aggregating devices in the equatorial areas.

SKJ-Figure 13. Changes in nominal CPUE for the European purse seiners in the eastern Atlantic (1970-2010). Free $=$ free schools ( $\mathrm{t} / \mathrm{f}$. day) off Senegal; FADs $=$ schools associated with fish aggregating devices ( $\mathrm{t} /$ successful set) in the equatorial area.

SKJ-Figure 14. Standardized CPUE for the main baitboat fleets operating in the eastern Atlantic Ocean: Azores, Canary islands (non standardized), Dakar and Ghana-based baitboats.

SKJ-Figure 15. Eastern skipjack stock status: trajectories of $B / B_{M S Y}$ and $F / F_{\text {MSY }}$ from the Bayesian surplus production model (Schaefer type), and from the generalized multi-fleets dynamic model.

SKJ-Figure 16. Standardized CPUEs of Brazilian baitboats, U.S. rod and reel recreational fleets and nonstandardized CPUE of the Venezuelan purse seiners in the western Atlantic Ocean.

SKJ-Figure 17. Western skipjack stock status: trajectories of $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\text {MSY }}$ from the Bayesian surplus production model (Schaefer type) and from Multifan-CL.

### 8.4 ALB - ALBACORE

The status of the North Atlantic albacore stock is based on the most recent analyses conducted in July 2009 by means of applying statistical modelling to the available data up to 2007. Complete information on the assessment can be found in the Report of the 2009 ICCAT Albacore Stock Assessment Session (Anon. 2010b).

The status of the South Atlantic and Mediterranean albacore stocks is based on the 2011 assessment using available data up to 2009 and 2010, respectively. Complete information is found in the Report of the 2011 ICCAT South Atlantic and Mediterranean Albacore Stock Assessment Session (SCRS/2011/019).

## ALB-1. Biology

Albacore is a temperate tuna widely distributed throughout the Atlantic Ocean and Mediterranean Sea. On the basis of the biological information available for assessment purposes, the existence of three stocks is assumed: northern and southern Atlantic stocks (separated at $5^{\circ} \mathrm{N}$ ) and Mediterranean stock (ALB-Figure 1). However, some studies support the hypothesis that various sub populations of albacore exist in the North Atlantic and Mediterranean. Likewise, there is likely intermingling of Indian Ocean and South Atlantic immature albacore which needs further research.

Scientific studies on albacore stocks, in the North Atlantic, North Pacific and the Mediterranean, suggest that environmental variability may have a serious potential impact on albacore stocks, affecting fisheries by changing the fishing grounds, as well as productivity levels and potential MSY of the stocks. Those unexplored aspects might explain recently observed changes in fisheries, such as the lack of availability of the resource in the Bay of Biscay in recent years, or the apparent decline in the estimated recruitment which are demanding focussed research.

The expected life-span for albacore is around 15 years. While albacore is a temperate species, spawning occurs in tropical waters. Present available knowledge on habitat, distribution, spawning areas and maturity of Atlantic albacore is based on limited studies, mostly from past decades. In the Mediterranean, there is a need to integrate different available studies so as to better characterize growth of Mediterranean albacore. Besides some additional recent studies on maturity, in general, there is poor knowledge about Mediterranean albacore biology and ecology.

More information on albacore biology and ecology is published in the ICCAT Manual.

## ALB-2. Description of fisheries or fisheries indicators

## North Atlantic

The northern stock is exploited by surface fisheries targeting mainly immature and sub-adult fish ( 50 cm to 90 cm FL) and longline fisheries targeting immature and adult albacore ( 60 cm to 130 cm FL). The main surface fisheries are carried out by EU fleets (Ireland, France, Portugal and Spain) in the Bay of Biscay, in the adjacent waters of the northeast Atlantic and in the vicinity of the Canary and Azores Islands in summer and autumn. The main longline fleet is the Chinese Taipei fleet which operates in the central and western North Atlantic year round. However, Chinese Taipei fishing effort decreased in late 1980s due to a shift towards targeting on tropical tuna, then continued at this lower level to the present. Over time, the relative contribution of different fleets to the total catch of North Atlantic albacore has changed, which resulted in differential effects on the age structure of the stock.

The historical time series of catch was extended back to 1930 for the troll fishery after revision of data for the assessment. Total reported landings for the North Atlantic generally began to decline after 1986, largely due to a reduction of fishing effort by the traditional surface (troll and baitboat) and longline fisheries (ALB-Table 1; ALB-Figure 2a). Some stabilization was observed in the 1990s, mainly due to increased effort and catch by new surface fisheries (driftnet and mid-water pair pelagic trawl), with a maximum catch in 2006 at $36,989 \mathrm{t}$ and, since then, a decreasing trend of catch is observed in the North Atlantic.

The total catch in 2010 was 19,649 t, representing an increase of $25 \%$ compared to the 2009 yield, which was the lowest recorded in the time series since 1950.

The surface fisheries accounted for the bulk of the total catch with 15,621 t reported in 2010 (81\%) (ALB-Table 1). The reported catch for EU-France in 2010 was $1,298 \mathrm{t}$, similar to 2009. The reported catch for EU-Spain in 2010 was $12,989 \mathrm{t}$, mainly from the troll fleet and baitboat fleets. This represents a $34 \%$ increase from the 2009 catch to a level similar to that in 2008. In contrast, EU-Ireland 2010 reported catches had decreased by $60 \%$ compared to 2009, reaching similar levels to those in the early 2000s.

Standardized catch rates of the Spanish troll fleet were updated to 2009. Albacore age 1 showed an increasing trend peaking in 2005 and 2006, fluctuating since then and a decrease in 2009. Age 2 albacore showed an increasing trend over the last years with a recent peak in 2008 and a decreasing trend in 2009. In the case of age 3, there is a continued upward trend from 2007 to 2009. Catch rates of the Irish mid-water pelagic trawl fleet showed a steep decline in 2007 compared to the higher estimates for 2005 and 2006.

In total, the 2010 longline catches increased compared to the last three years. The Chinese Taipei preliminary catch in 2010 was $1,587 \mathrm{t}$, an increase as compared to that of 2009, which was a low catch year stemming mainly from a reduction in fishing effort. Japan takes albacore as by-catch with longline gear. The Japanese longline preliminary catch reached 515 t in 2010, which represented an increase from 2009 in spite of the reducing fishing effort during the last decades. The catch fluctuated from around 300 t to $1,300 \mathrm{t}$ in the last decade. Recent catch rates from the Chinese Taipei longline fishery in 2008 showed the same level as in 2007.

The trend in mean weight for all surface fleets (baitboat, troll, mid-water, pair pelagic and other surface) from 1975 to 2007 showed a stable trend with an average of 7 kg (range:4-10). For longline fleets from 1975 to 2005 the mean weight was also relatively stable with an average of 18.8 kg (range: 13.4-25.7 kg) (ALB-Figure 3a).

## South Atlantic

The recent total annual South Atlantic albacore landings were largely attributed to four fisheries, namely the surface baitboat fleets of South Africa and Namibia, and the longline fleets of Brazil and Chinese Taipei (ALBTable 1; ALB-Figure 2b). The surface fleets are entirely albacore directed and mainly catch juvenile and subadult fish ( 70 cm to 90 cm FL). These surface fisheries operate seasonally, from October to May, when albacore are available in coastal waters. Brazilian longliners target albacore during the first and fourth quarters of the year, when an important concentration of adult fish (> 90 cm ) is observed off the northeast coast off Brazil, between $5^{\circ} \mathrm{S}$ and $20^{\circ} \mathrm{S}$, being likely related to favorable environmental conditions for spawning, particularly of sea surface temperature. The longline Chinese Taipei fleet operates over a larger area and throughout the year, and consists of vessels that target albacore and vessels that take albacore as by-catch, in bigeye directed fishing operations. On average, the longline vessels catch larger albacore ( 60 cm to 120 cm FL) than the surface fleets.

Total reported albacore landings for 2010 were $18,900 \mathrm{t}$, a decrease of about $19 \%$ from 2009 catch. The Chinese Taipei preliminary catch in 2010 was $10,975 \mathrm{t}$, an increase of $2,297 \mathrm{t}$ as compared to that of 2009. However, the Chinese Taipei catch in the last years has decreased mainly due to a decrease in fishing effort targeting albacore. Chinese Taipei longliners (including boats flagged in Belize and St. Vincent and the Grenadines) stopped fishing for Brazil in 2003, which resulted in albacore only being caught as by-catch in tropical tuna-directed longline fisheries. Albacore is only caught as by-catch in Brazilian tropical tuna-directed longline and baitboat fisheries. In 2010, the catch of the Brazilian fishery was 271 t , showing an increase of about $35 \%$ compared to 2009. The average catch of about $4,287 \mathrm{t}$ during the period 2000-2003 was obtained by the Brazilian longline fleet when albacore was a target species. In 2009, Uruguay reported 685 t , which represent an extremely high increase from previous reported years. Reported catch in 2010 ( 24 t ) was, however, on the order of magnitude of earlier years.

In 2010, the estimated South African catch was $4,147 \mathrm{t}$ (mainly baitboat), which represented a decrease of about $18 \%$ from 2009. In addition, in 2010 the Namibian total reported catch was $1,320 \mathrm{t}$ (mainly baitboat), a decrease of $74 \%$ from 2009. Japan takes albacore as by-catch using longline gear. In 2010, the Japanese longline preliminary catch was $1,007 \mathrm{t}$, an increase of $9 \%$ from 2009. The relatively large increase from 238 t in 2007 was due to an increase in fishing effort in the waters off southern Africa ( $20-40^{\circ} \mathrm{S}$ ).

The trend in mean weight from the 1975 to 2009 period is shown in ALB-Figure 3b. Surface fleets showed a stable trend from 1981 onwards with an average of 12.7 kg and a maximum and minimum weight of 16.5 kg and 10 kg , respectively. While the trend in mean weight for longline fisheries showed an increase after 1996.

## Mediterranean

The catch series was revisited and compared to additional sources of information. This allowed identifying some catches that were not included in the ICCAT database, which requires further revisions. In 2010, the reported
landings were 2,123 t, a 47\% decrease from 4,021 t taken in 2009 (ALB-Table 1 and ALB-Figure 2c). The majority of the catch came from longline fisheries. EU-Italy is the main producer of Mediterranean albacore and in 2010 the Italian catch was $1,109 \mathrm{t}$, a $60 \%$ reduction from its 2009 catch.

## ALB-3. State of stocks

## North Atlantic

A thorough revision of North Atlantic Task I and Task II data was conducted and a more robust method for catch-at-size analyses was implemented for the 2009 assessment session similar to that used in the 2007 assessment. In addition, catch rate analyses were improved and updated with new information for the northern albacore fisheries and substantial effort was undertaken to implement assessment methods which do not assume that catch-at-age is perfectly known. The analyses were also conducted to incorporate longer time-series of catch, effort and size information into the assessment to guide the evaluation. The approach provided the opportunity to evaluate a range of hypothesis about how the fisheries operated over time and their impact on the population. The results of these efforts are reflected in the following summaries of stock status that analyzed data through 2007.

The CPUE trends for the various surface fleets, based upon the most recent available 2007 data showed somewhat different patterns from each other. This was also the case for the different longline fleets (ALBFigure 4). The Spanish age two troll CPUE series showed evidence of a relatively strong 2003 year class entering the fishery. For the Spanish age three troll CPUE series, the age signal is not as strong, leading to uncertainty about the possibility of a good year class. For the longline fleets, the general trend in CPUE indices is a decline over time, with varying rates. Given the variability associated with these catch rate estimates, definitive conclusions about recent trends could not be reached just by examining the CPUE trends alone which represent different parts of the population.

The data sets used for the analyses from 1930 to 2007 were compiled during the July 2009 stock assessment meeting. The data was classified into 10 fishery units using the same definitions as those used in the 2007 stock assessment. The basic input data, catch, effort and catch-at-size were revised due to updates in the ICCAT Task I (Table 1) and Task II database. Model specification for the base case was identical to the 2007 assessment. However, the model was run using the latest version of the software. Different hypothesis on the dynamics of the northern albacore stock were tested and those with clearly unrealistic outputs were discarded.

Based on the present assessment which considers catch and effort since the 1930s and size frequency since 1959, the view of the northern albacore resource status is that spawning stock size has declined and in 2007 was about one third of the peak levels estimated for the late-1940s. Estimates of recruitment to the fishery, although variable, have shown generally higher levels in the 1960s and earlier periods with a declining trend thereafter until 2007. The most recent recruitment is estimated to be the lowest for all the years of the evaluation although the magnitude of this year-class is highly uncertain in the latest year (ALB-Figure 5). The 2009 current assessment indicated that the stock has remained below $\mathrm{B}_{\mathrm{MSY}}$ (current $\mathrm{SSB}_{2007}$ is approximately $62 \%$ of SSB at MSY) (ALB-Figure 5) since the late 1960. Corresponding fishing mortality rates have been above $\mathrm{F}_{\text {MSY }}$ (current $\mathrm{F}_{2007} / \mathrm{F}_{\mathrm{MSY}}$ ratio is 1.05 which is only slightly higher than $\mathrm{F}_{\text {MSY }}$, ALB-Figure 6).

The trajectory of fishing mortality and spawning stock biomass relative to MSY reference points, from the assessment model is shown in ALB-Figure 6. As the majority of the time series is in the top left quadrant $\left(\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}>1\right.$ and, $\left.\mathrm{SSB} / \mathrm{SSB}_{\mathrm{MSY}}<1\right)$ this could indicate the northern albacore stock has been overfished ( $\mathrm{SSB} / \mathrm{SSB}_{\mathrm{MSY}}<1$ ) since the mid-1980s. Uncertainty around the estimates of current $\mathrm{F}_{2007} / \mathrm{F}_{\mathrm{MSY}}$ and $\mathrm{SSB}_{2007} / \mathrm{SSB}_{\mathrm{MSY}}$ is shown in ALB-Figure 7.

## South Atlantic

In 2011, a stock assessment of South Atlantic albacore was conducted including catch, effort and size data up until 2009, and considering a broader range of methods than in the previous assessment.

The southern standardized CPUE trends are mainly for longline fisheries, which harvest mostly mature albacore. The longest time series (those of Japan and Chinese Taipei), showed a strong declining trend in the early part of the time series, and less steep decline over the past decade. However, the Brazilian and Uruguayan longline CPUE series showed significant decreases in the late 1990s. The CPUE from the recent South African baitboat fishery, harvesting mostly juvenile albacore, shows no apparent trend (ALB-Figure 8).

In the 2011 assessment, eight scenarios were considered. Stock status results varied significantly among them (ALB-Figure 9). In general, two different production model forms were considered. One showed more optimistic results than the other. However, the Committee lacked enough objective information to identify the most plausible scenarios. Considering the whole range of scenarios, the median MSY value was $27,964 \mathrm{t}$ (ranging between $23,296 \mathrm{t}$ and $98,371 \mathrm{t}$ ), the median estimate of current $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ was 0.88 (ranging between 0.55 and 1.59) and the median estimate of current $\mathrm{F} / \mathrm{F}_{\text {mSY }}$ was 1.07 (ranging between 0.44 and 1.95 ). The wide confidence intervals reflect the large uncertainty around the estimates of stock status. Considering all scenarios, there is $54 \%$ probability for the stock to be both overfished and experiencing overfishing, $10 \%$ probability for the stock to be either overfished or experiencing overfishing, and $36 \%$ probability that biomass is above and fishing mortality is below the Convention objectives.

## Mediterranean

In 2011, the first stock assessment for Mediterranean albacore was conducted, using data up until 2010. The methods used were adapted to the "data poor" category of this stock. The more data-demanding methods applied, such as a production model, gave unrealistic results.

Some CPUE series for Mediterranean fisheries became available (ALB-Figure 10). However, these series were discontinuous and highly variable, with no clear trend over the last couple of decades. Since they are mostly very short, and there is little overlap between time series, they may or may not accurately characterize biomass dynamics in Mediterranean albacore.

The results of the 2011 assessment, based on the limited information available and in simple analyses, point to a relatively stable pattern for albacore biomass in the recent past. Recent fishing mortality levels appear to have been reduced from those of the early 2000s, which were likely in excess of $\mathrm{F}_{\text {MSY }}$, and might now be at about or lower that level (ALB-Figure 11).

## ALB-4. Outlook

## North Atlantic

Using the reference points calculated by the current base case assessment model done in 2009, projections indicate that constant catches above 28,000 t will not result in stock rebuilding to Convention standards by 2020 (ALB-Figure 12). Since 2008 catches have been lower than $28,000 \mathrm{t}$.

## South Atlantic

The projection results differ between the base case scenarios. Since there is not objective information with which to select which scenario is more plausible, the group considered the entire range of scenarios, thus characterizing the range of possible responses, for part of the stock, to the distinct catch levels projected, depending on the scenario. Projections showed that harvesting at the current TAC level ( $29,900 \mathrm{t}$ ) would further decline the stock. However, if catches continue at the level of those experienced in the last few years, there is more than $50 \%$ probability to recover the stock in 5 years, and more than a $60 \%$ probability to do so in 10 years (ALB-Figure 13).

## Mediterranean

Due to the fact that the management advice for the Mediterranean stock was based on catch curve analysis and due to the limited quantitative information available to the SCRS, projections for this stock were not conducted. As a result, future stock status in response to management actions could not be simulated. The outlook for this stock is thus unknown.

## ALB-5. Effects of current regulations

## North Atlantic

In 2009, the Commission established a new TAC for 2010 and 2011 of 28,000 t [Rec. 09-05], but included several provisions that allow the catch to exceed this level.

Furthermore, a 1998 recommendation that limits fishing capacity to the average of 1993-1995, remains in force. The Committee noted that, since 2008, the reported catches were below the recommended TACs (ALB-Table 1).

## South Atlantic

In 2007 the Commission established a new TAC from 2008 to 2011 of 29,900 t [Rec. 07-03]. The Committee noted that reported catches in 2009 and 2010 were well below the TAC (ALB-Table 1).

## Mediterranean

There are no ICCAT regulations directly aimed at managing the Mediterranean albacore stock.

## ALB-6. Management recommendations

## North Atlantic

In 2007, the Commission implemented [Rec. 07-02], intended to reduce the TAC to 30,200 t in 2008 and 2009 and allow the rebuilding of the northern albacore stock from the overfished condition. However, it was reiterated that the fishing opportunities provided in [Rec. 07-02] allow the potential catch to exceed the TAC (ALB-Figure 2a). In view of the 2009 assessment, in order to achieve the Commission management objective by 2020, a level of catch of no more than $28,000 \mathrm{t}$ will be required. The Commission recommended the establishment of a Total Allowable Catch (TAC) of 28,000 t for 2010 and 2011 [Rec. 09-05].

## South Atlantic

There is considerable uncertainty about the current stock status, as well as on the effect of alternative catch limits on the rebuilding probabilities of the southern stock. Results indicate that, most probably, the South Atlantic albacore stock is both overfished and experiencing overfishing. Projections showed that harvesting at the current TAC level ( $29,900 \mathrm{t}$ ) would further decline the stock. However, if catches continue at the level of those experienced in the last few years (around $20,000 \mathrm{t}$ ), there is more than $50 \%$ probability to recover the stock in 5 years, and more than a $60 \%$ probability to do so in 10 years. Further reductions in catches would increase the probability of recovery in those timeframes. And likewise, increases would reduce rebuilding probabilities and extend the timeframes. Catches over $24,000 \mathrm{t}$ will not permit the rebuilding of the stock with at least $50 \%$ probability over the projection timeframe (ALB-Table 2).

## Mediterranean

The available information on Mediterranean albacore stock status indicates a relatively stable pattern for albacore biomass over the recent past. Unfortunately, very little quantitative information is available to SCRS for use in conducting a robust quantitative characterization on biomass status relative to Convention objectives. While additional data to address this issue might exist at CPC levels, our ability to provide quantitative management advice will be seriously impeded until such data become available either through recovery of historical data or institution of adequate fishery monitoring data collection programs. Recent fishing mortality levels appear to have been reduced from those of the early 2000s, which were likely in excess of $\mathrm{F}_{\mathrm{MSY}}$, and might now be at about or lower than that level. However, there is considerable uncertainty about this and for this reason, the Commission should institute management measures designed to limit increases in catch and effort directed at Mediterranean albacore.

## ATLANTIC AND MEDITERRANEAN ALBACORE SUMMARY

|  | North Atlantic | South Atlantic | Mediterranean |
| :---: | :---: | :---: | :---: |

ALB-Figure 4. North Atlantic albacore. Standardized catch rate indices used in the 2009 northern albacore stock assessment from the surface fisheries (upper panel), which take mostly juvenile fish, and from the longline fisheries (lower panel), which take mostly adult fish.

ALB-Figure 5. North Atlantic albacore. Estimates of northern Atlantic albacore recruitment (age 1) and spawning stock size from 1930-2007 from Multifan-CL model assessment. Uncertainty in the estimates has not been characterized, but the uncertainty in recent recruitment levels is considered to be higher than in the past.

ALB-Figure 6. North Atlantic albacore. Stock status of northern albacore, estimated with Multifan-CL. Top: Relative biomass ( $\mathrm{SSB} / \mathrm{SSB}_{\text {MSY }}$ ) and relative fishing mortality ( $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ ) trajectories over time. Bottom: joint trajectories of $\mathrm{SSB} / \mathrm{SSB}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$. The red X cross in the lower panel represents the stock status in 2007.

ALB-Figure 7. North Atlantic albacore. Uncertainty in current stock status for northern albacore, as estimated from the Multifan base case model. The X represents the current (2007) estimates of fishing mortality and spawning biomass ratios, and the scatter of points depicts uncertainty in that estimate.

ALB-Figure 8. South Atlantic albacore. Standardized catch rates indices used in the 2011 southern albacore stock assessment from the longline fisheries, which take mostly mature fish, and from the surface fisheries (South African baitboat), which take mostly juvenile fish.

ALB-Figure 9. South Atlantic albacore. Upper panel: Median biomass and fishing mortality rates relative to MSY levels, with $50 \%$ credibility intervals, from the 4 base case Bayesian Surplus Production (BSP) models and the point estimate biomass and $50 \%$ credibility intervals for the 4 base case ASPIC Production models. Lower panel: Stock status trajectories of $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$, as well as uncertainty around the current estimate (Kobe plots) for the base case ASPIC models (Runs $2,6,7$ and 8 ) alongside those from the base case BSP runs (1, 4, 12 and 13).

ALB-Figure 10. Mediterranean albacore. Set of standardized and nominal CPUEs used in the assessment of the Mediterranean albacore stock. The "Greek by-catch" indicates the probability of albacore by-catch in the swordfish fishery, practically null in some years. This series is the only one that is not included in the base case Bayesian production model.

ALB-Figure 11. Mediterranean albacore. Estimates of equilibrium fishing mortality rate relative to $M$ (as a proxy for $\mathrm{F}_{\mathrm{MSY}}$, based on length-converted catch curve analysis. The central solid line represents an M assumption of 0.3 with patterns resulting from an assumed M of 0.4 (lower dashed) and 0.2 (upper dashed) also depicted.

ALB-Figure 12. North Atlantic albacore. Estimated projections of relative SSB ( $\mathrm{SSB} / \mathrm{SSB}_{\mathrm{MSY}}$ ) for different scenarios of constant catch (20,000-36,000 t) assuming average recent year-class strengths for the North Atlantic albacore stock. Projections assumed a catch of 30,200 t in 2008 and 2009.

ALB-Figure 13. South Atlantic albacore. Upper panel: "Kobe plots" by Run for TAC projections; lines are the median stock trajectories. Quadrants are defined for the stock biomass and fishing mortality relative to $\mathrm{B}_{\text {MSY }}$ and $\mathrm{F}_{\mathrm{MSY}}$; i.e. red if $\mathrm{SSB}<\mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F}>\mathrm{F}_{\text {MSY }}$, green if $\mathrm{SSB} \geq \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} \leq \mathrm{F}_{\text {MSY }}$, and yellow otherwise. Lower panel: Kobe strategy matrix ( K 2 SM ) advice plot. Contours correspond to the probability of being in the Kobe quadrant corresponding to $S S B \geq B_{\text {MSY }}$ and $F \leq F_{M S Y}$ by year for each of the TAC levels, integrated over all runs with equal probability.

### 8.5 BFT - ATLANTIC BLUEFIN TUNA

The SCRS conducted a comprehensive assessment of bluefin tuna in the Atlantic and the Mediterranean in 2010 (Anon. 2011c). In the assessment, the available data included catch, effort and size statistics through 2009. As previously discussed, there are considerable data limitations for the eastern stock up to 2007. While data reporting for the eastern and Mediterranean fisheries have substantially improved since 2008 and some historical statistical data have been recovered, nonetheless, most of the data limitations that have plagued previous assessments remain and will require new approaches in order to improve the scientific advice the Committee can offer.

The Atlantic-wide Research Programme on Bluefin Tuna (GBYP) research plan outlined the research necessary for improving the scientific advice that the Committee provides to the Commission. This plan was presented to and approved by the Commission and the GBYP was started in 2010. The Committee continues to strongly and unanimously support the GBYP, and welcomes the Commission's continued commitment to the Program. In the absence of such a significant and sustained effort, it remains highly unlikely that the Committee will improve its scientific diagnosis and management advice in the foreseeable future.

In 2011, the SCRS updated the fisheries statistics and some CPUE indices up to 2010 and reviewed new information on the biology, spatial dynamics and various approaches to survey the catch. The SCRS also discussed progress done by the GBYP and the BFT US research program about the aerial survey, tagging, data mining, biological sampling, stock mixing and new modeling approaches. These new documents are summarized in SCRS/2011/203.

## BFT-1. Biology

Atlantic bluefin tuna (BFT) mainly live in the pelagic ecosystem of the entire North Atlantic and its adjacent seas, primarily the Mediterranean Sea. Bluefin tuna have a wide geographical distribution living mostly in temperate Atlantic waters and adjacent seas (BFT-Figure 1). Archival tagging and tracking information confirmed that bluefin tuna can sustain cold as well as warm temperatures while maintaining stable internal body temperature. Until recently, it was assumed that bluefin tuna preferentially occupy the surface and subsurface waters of the coastal and open-sea areas, but archival tagging and ultrasonic telemetry data indicate that bluefin tuna frequently dive to depths of 500 m to $1,000 \mathrm{~m}$. Bluefin tuna is also a highly migratory species that seems to display a homing behavior and spawning site fidelity in both the Mediterranean Sea and Gulf of Mexico, which constitute the two main spawning areas being clearly identified today. Less is known about feeding migrations within the Mediterranean and the North Atlantic, but results from electronic tagging indicated that bluefin tuna movement patterns vary considerably between individuals, years and areas. The appearance and disappearance of important past fisheries further suggest that important changes in the spatial dynamics of bluefin tuna may also have resulted from interactions between biological factors, environmental variations and fishing. Although the Atlantic bluefin tuna population is managed as two stocks, conventionally separated by the $45^{\circ} \mathrm{W}$ meridian, its population structure remains poorly understood and needs to be further investigated. Recent genetic and microchemistry studies as well as work based on historical fisheries tend to indicate that the bluefin tuna population structure is complex.

Currently, bluefin tuna is assumed to mature at approximately 25 kg (age 4) in the Mediterranean and at approximately 145 kg (age 9) in the Gulf of Mexico. Juvenile and adult bluefin tuna are opportunistic feeders (as are most predators). However, in general, juveniles feed on crustaceans, fish and cephalopods, while adults primarily feed on fish such as herring, anchovy, sand lance, sardine, sprat, bluefish and mackerel. Juvenile growth is rapid for a teleost fish (about $30 \mathrm{~cm} /$ year), but slower than other tuna and billfish species. Fish born in June attain a length of about $30-40 \mathrm{~cm}$ long and a weight of about 1 kg by October. After one year, fish reach about 4 kg and 60 cm long. Growth in length tends to be lower for adults than juveniles, but growth in weight increases. At 10 years old, a bluefin tuna is about 200 cm and 170 kg and reaches about 270 cm and 400 kg at 20 years. Bluefin tuna is a long lived species, with a lifespan of about 40 years, as indicated by recent studies from radiocarbon deposition.

The information on natal origin derived from otolith microchemistry received by the SCRS indicated that there is, based on samples covering a limited number of years, a greater contribution of eastern origin fish to the western fisheries with decreasing average size of the fish in the catch (i.e. up to $62 \%$ for fish in the 69-119 cm size class). In contrast, other western fisheries supported by the largest size classes had minimal or no eastern component in the catch. However, there remains considerable uncertainty and therefore additional samples are
needed to improve our understanding of the relative contribution of the two stocks to the different fisheries over time --an issue that can hardly be resolved without better understanding of Atlantic bluefin tuna population structure.

The SCRS had extensive discussions concerning the choice of maturity schedules for both the eastern and western stocks. Uncertainty in age at maturity remained a significant issue for the stock assessment, and obliged the Group to consider alternative scenarios during their modeling work. Improving current understanding of the maturity schedules for bluefin tuna should be a priority area for research within the GBYP and other collaborative research programs with the SCRS.

The SCRS implemented a new growth curve for western stock that was derived from advanced analytical techniques. The adoption of the new growth curve that is nearly identical to that for the eastern stock has resulted in significant changes to some of the benchmark for the western stock and consequently management advice. For the eastern Atlantic and Mediterranean stock, new information indicated that for farming operations, when applying the weight gain rates adopted by SCRS in 2009, the back calculated fish weights at initial capture seemed to show unrealistic size distributions, in that more fish of a smaller size are calculated as having been caught than would be expected given existing controls. In 2011, the SCRS had extensive discussion about the growth curve for the eastern stock and concluded that the considerable amount of new information on hard parts from national programs and the GBYP will help in reducing uncertainties in catch-at-age matrix in the near future.

The SCRS also received several contributions related to electronic tagging within the Eastern Atlantic and Mediterranean stock. While most of the new studies are reporting work in progress, the new information appears to indicate a greater level of complexity in the migratory patterns of the eastern fish than was previously understood, as a significant fraction of the eastern fish (juveniles and spawners) seem to stay within the Mediterranean all year long.

## BLUEFIN TUNA - EAST

## BFTE-2. Fishery trends and indicators - East Atlantic and Mediterranean

It is very well known that introduction of fattening and farming activities into the Mediterranean in 1997 and good market conditions resulted in rapid changes in the Mediterranean fisheries for bluefin tuna mainly due to increasing purse seine catches. In the last few years, nearly all of the declared Mediterranean bluefin fishery production was exported overseas. Declared catches in the East Atlantic and Mediterranean reached a peak of over 50,000 t in 1996 and, then decreased substantially, stabilizing around TAC levels established by ICCAT for the most recent period (BFT-Table 1 and BFTE-Figure 1). Both the increase and the subsequent decrease in declared production occurred mainly for the Mediterranean (BFTE-Figure 1). For 2006-2010, declared catch was, at the time of the meeting, $30,689 \mathrm{t}, 34,516 \mathrm{t}, 23,849 \mathrm{t}, 19,701 \mathrm{t}$ and $11,294 \mathrm{t}$ for the East Atlantic and Mediterranean, of which 23,154 t, 26,479 t, 16,205 t, 13,016 t and 6,949 t were declared for the Mediterranean for those same years (BFT-Table 1).

Information available has demonstrated that catches of bluefin tuna from the East Atlantic and Mediterranean were seriously under-reported between the mid-1990s through 2007. The Committee views this lack of compliance with TAC and underreporting of the catch as having undermined conservation of the stock. The Committee has estimated that realized catches during this period could have been on the order of $50,000 \mathrm{t}$ to $61,000 \mathrm{t}$ per year based on the number of vessels operating in the Mediterranean Sea and their respective catch rates. Estimates for 2008 and 2009 using updated vessel capacity and performance statistics from the various reports submitted to ICCAT under [Rec. 08-05] results in estimates that are significantly lower than the corresponding reported Task I data (see Report of the Bluefin Tuna Data Preparatory Meeting) (Anon. 2011d). Although care is needed considering estimates of catch using these capacity measures, the Committee's interpretation is that a substantial decrease in the catch occurred in the eastern Atlantic and Mediterranean Sea in 2008 and 2009. Declared catches in 2010 were significantly below the 2010 TAC of 13500 t. However, some CPCs did not report their 2010 catch. To complete this lacking information, the SCRS used the information from the BCD that were still largely incomplete at the time of the meeting.

Available indicators from small fish fisheries in the Bay of Biscay did not show any clear trend since the mid1970s (BFTE-Figure 2). This result is not particularly surprising because of strong inter-annual variation in year class strength. However, aerial survey results conducted in 2009 indicated a higher abundance or higher
concentration of small bluefin in the northwestern Mediterranean than found in surveys conducted in 2000-2003. Indicators from Japanese longliners and Spanish and Moroccan traps targeting large fish (spawners) in the East Atlantic and the Mediterranean Sea displayed a recent increase after a general decline since the mid-1970s (BFTE-Figure 2). Indicators from longliners targeting medium to large fish in the northeast Atlantic were available since 1990 and showed an increasing trend in the recent years (BFTE Figure 2). This index becomes more valuable since the major part of Japanese catch come from this fishing ground in recent years, while the activities of longliners in the East Atlantic (south of 40N) and Mediterranean Sea were reduced. The preliminary updates of the CPUE indices and aerial surveys until 2010 confirm these positive trends in recent years.Two historical indicators before 1980 in the Bay of Biscay were also available. The SCRS recognized that the recent compliance to the regulatory measures affect significantly the CPUE values (e.g. Spanish baitboat and Japanese longline indices) through the change of operational pattern and target sizes. Recent tendency in indicators are likely to reflect positive outcomes from recent management measures. However, the Committee found it difficult to derive any clear conclusion from fisheries indicators over such a short period after the implementation of new regulations and in the absence of more precise information about the catch composition, effort and spatial distribution of the purse seine fisheries. Fisheries-independent indicators (scientific surveys) and a large scale tagging program are needed to provide more reliable stock status indicators. The Committee reaffirmed the importance of pursuing these research elements under the now-funded GBYP.

## BFTE-3. State of the stock

In spite of improvements in the data quantity and quality for the past few years, there remain considerable data limitations for the 2010 assessment of the stock. These included poor temporal and spatial coverage for detailed size and catch-effort statistics for many fisheries, especially in the Mediterranean. Substantial under-reporting of total catches was also evident, especially during the years 1998-2007. Nevertheless, the Committee assessed the stock in 2010 as requested by the Commission mainly applying the methodologies and hypotheses adopted by the Committee in previous assessments and further tried alternative approaches. The Committee believes that while substantial improvements can be made for in catch and effort statistics into the future, it appears unlikely that such substantial improvements can be made regarding historical fishery performance. Because of this, the Committee believes that assessment methodologies applied in the past must be modified to better accommodate the substantial uncertainties in the historical total catch, catch-at-age and effort data from the main fleets harvesting bluefin. This process has been initiated, but will require at least 3 years to complete in terms of robustness testing of the methodologies envisioned. The Commission should take this into account in establishing management controls. Furthermore, any change in exploitation or management will take several years to have a detectable effect on the biomass because bluefin tuna is a long lived species and our ability to quantify recent management impacts on stock status are limited due to variability in stock status indicators in the most recent years.

The assessment results upon which the Committee's main advice is provided indicated that the spawning stock biomass (SSB) had been mostly declining since the 1970s. The recent SSB tendency has shown signs of increase/stabilization in some runs while it continues to decline for others, depending on the models specifications and data used (see Bluefin Tuna Detailed Report, BFTE-Figure 3). Trend in fishing mortality (F) displayed a continuous increase over the time period for the younger ages (ages 2-5) while for oldest fish (ages $10+$ ) it had been decreasing during the first 2 decades and then rapidly increased during the 1990s. Fishing mortalities have declined on the oldest fish in recent years, but these for younger (ages 2-5) are more uncertain and display higher variability (BFTE-Figure 3). General trends in F or N were not strongly affected by the historical catches assumptions (i.e. reported versus inflated), except in recent years. These analyses indicated that recent (2007-2009) SSB is about $57 \%$ of the highest estimated SSB levels (1957-1959). Recent recruitment levels remain very uncertain due to the lack of information about incoming year class strength and high variability in the indicators used to track recruitment and the low recent catches of fish less than the minimum size. The absolute values estimated for F and SSB remained sensitive to the assumptions of the analysis and could lead to a different perception in the whole trend in SSB. However, it is noteworthy that the historical Fs for older fish were consistent between different types of models which made use of different assumptions. For the period 1995-2007, Fs for older fish are also consistent with a shift in targeting towards larger individuals destined for fattening and/or farming.

Estimates of current stock status relative to MSY benchmarks are uncertain, but lead to the conclusion that although the recent Fs have probably declined, these values remain too high and recent SSB too low to be consistent with the Convention objectives. Depending on different assumed levels of resource productivity current F show signs of decline reflecting recent catch reductions, but remained larger than that which would
result in MSY and SSB remained most likely to be about 35\% (from 19\% to 51\% depending on the recruitment levels) than the level needed to support MSY (BFTE-Figure 4).

## BFTE- 4. Outlook

During the last decade, there has been an overall shift in targeting towards large bluefin tuna, mostly in the Mediterranean. As the majority of these fish are destined for fattening and/or farming operations, it is crucial to get precise information about the total catch, the size composition, the area and flag of capture. Progress has been made over the last years, but current information that consists in individual weight after fattening remain too uncertain to be used within stock assessment models. Therefore, real size samples at time of the catch are still required. Pilot studies using dual camera systems have been presented at the SCRS in 2011 (see SCRS/2011/173 and SCRS/2011/191). The results are encouraging and the SCRS strongly encourages the CPCs to finalize these studies, so that stereoscopic camera systems became operational as soon as possible.

The shift towards larger fish should result in improved yield-per-recruit levels in the long-term if $F$ were reduced to $F_{0.1}$. However, such changes would take several years to translate into gains in yield due to the longevity of the species. Realization of higher long-term yields would further depend on future recruitment levels.

Even considering uncertainties in the analyses, the outlook derived from the 2010 assessment has improved in comparison to previous assessments, as F for older fish seem to have significantly declined during the last two years. However, estimates in the last years are known to be more uncertain and this decline (as the Fs for younger ages which remains more variable) needs to be confirmed in future analyses. Nonetheless, $\mathrm{F}_{2009}$ still remains largely above the reference target $\mathrm{F}_{0.1}$ (a reference point more robust to uncertainties than $\mathrm{F}_{\text {MAX }}$, as used in the past) while SSB is only about $35 \%$ of the biomass that is expected under a MSY strategy (BFTE-Figure 4).

The Committee also evaluated the potential effects of [Rec. 09-06]. Acknowledging that there is insufficient scientific information to determine precisely the productivity of the stock (i.e. the steepness of the stockrecruitment relationship), the Committee agreed to perform the projections with three recruitment levels while taking into account for year-to-year variations. These levels correspond to the 'low' and 'high' scenarios as defined in the 2008 assessment plus a 'Medium' scenario that corresponds to the geometric mean of the recruitment over the 1950-2006 years. For the projections, the group investigated 24 scenarios (see the 2010 Bluefin Tuna Stock Assessment Report) (Anon. 2011c). The results indicated that the stock is increasing in all the cases, but the probability to achieve $\mathrm{SSB}_{\mathrm{F0.1}}$ (i.e. the equilibrium SSB resulting in fishing at $\mathrm{F}_{0.1}$ ) by the end of 2022 depend on the scenarios (run 13 leads to slower rebuilding than run 15 while the recruitment levels affect both the speed of rebuilding and the level of depletion, see Bluefin Tuna Detailed Report). Overall, the SSB would be equal or greater than $\mathrm{SSB}_{\mathrm{F} 0.1}$ by the end of 2022 for a catch $=0$ to $13,500 \mathrm{t}$, but not when the catch is greater than 14,000 t (BFTE-Table 1, BFTE-Figure 5). It is finally worth noting that a $\mathrm{F}_{0.1}$ strategy would not allow the rebuilding of the stock to $\mathrm{SSB}_{\mathrm{F} 0.1}$ by 2022, but later on.

Projections are known to be impaired by various sources of uncertainties that have not yet been quantified. Although the situation has improved regarding recent catch, there are still uncertainties about stock status in 2009, population structure and migratory rates as well as a lack of knowledge about the level of IUU catch and key modeling parameters on bluefin tuna productivity. Acknowledging these limitations, the overall evaluation of [Rec. 09-06] indicated that the rebuilding of eastern bluefin tuna at SSB $_{\mathrm{F} 0.1}$ level with a probability of at least $60 \%$ could be achieved by 2019 with zero catch and by 2022 with catch equal to current TAC (i.e. 13,500 t). However, this $60 \%$ probability level is unlikely to be attained by the end of 2022 with a catch greater than $14,000 \mathrm{t}$. Finally, it should be noted that the incorporation of additional uncertainties into the overall analysis could change the estimates of rebuilding probability.

## BFTE-5. Effect of current regulations

Catch limits have been in place for the eastern Atlantic and Mediterranean management unit since 1998. In 2002, the Commission fixed the Total Allowable Catch (TAC) for the East Atlantic and Mediterranean bluefin tuna at $32,000 \mathrm{t}$ for the years 2003 to 2006 [Rec. 02-08] and at 29,500 t and 28,500 t for 2007 and 2008, respectively [Rec. 06-05]. Subsequently, [Rec. 08-05] established TACs for 2009, 2010, and 2011 at 22,000 t, 19,950 t, and $18,500 \mathrm{t}$, respectively. However, the 2010 TAC was revised to $13,500 \mathrm{t}$ by [Rec. 09-06] which also established a framework to set future (2011 and beyond) TAC at levels sufficient to rebuild the stock to $\mathrm{B}_{\text {MSY }}$ by 2022 with at least $60 \%$ probability. The 2011 TAC was set at $12,900 \mathrm{t}$ by [Rec 10.04].

The reported catches for 2003, 2004 and 2006 were about TAC levels, but those for 2005 ( $35,845 \mathrm{t}$ ) and 2007 ( $34,516 \mathrm{t}$ ) were notably higher than TAC. However, the Committee strongly believes, based on the knowledge of the fisheries and trade statistics, that substantial under-reporting was occurring and that actual catches up to 2007 were well above TAC. The SCRS estimates since the late-1990s, catches were close to the levels reported in the mid-1990s, but for 2007, the estimates were higher i.e. about $61,000 \mathrm{t}$ in 2007 for both the East Atlantic and Mediterranean Sea. As noted, reported catch levels for 2008 (24,057 t), 2009 (20,228 t) and 2010 (11,294 t) appear to largely reflect the removals from the stock when comparing estimates of catch using vessel capacity measures, although the utility of this method has diminished for estimating catch. The reported catches for 2008, 2009 and 2010 are 10,000 $t$ to 25,000 t lower than the 2003-2007 reported catches (BFT-Table 1, BFTE-Figure 1). Although care is needed considering estimates of catch using capacity measures, the Committee's interpretation is that a substantial decrease in the catch occurred in the eastern Atlantic and Mediterranean Sea through implementation of the rebuilding plan and through monitoring and enforcement controls. While current controls appear sufficient to constrain the fleet to harvests at or below TAC, the Committee remains concerned about substantial excess capacity remains which could easily harvest catch volumes well in excess of the rebuilding strategy adopted by the Commission.

Recent analyses from the reported catch-at-size and catch-at-age displayed important changes in selectivity patterns over the last three years for several fleets operating in the Mediterranean Sea or the East Atlantic. This partly results from the enforcement of minimum size regulations under Rec.[06.05] which led to much lower reported catch of younger fish and subsequently a steep increase in the annual mean-weight in the catch-at-size since 2007 (BFTE-Figure 5). Additionally, higher abundance or higher concentration of small bluefin tuna in the northwestern Mediterranean detected from aerial surveys could also reflect positive outcomes from increase minimum size regulation.

While several fishery indicators have shown some positive tendency in the most recent fishing seasons, the available catch effort statistics are not yet sufficient to permit the Committee to quantify the extent of impact of the recent regulations on the overall stock with precision. The Committee's view is that it will take additional years under constrained fishing before to measure it more precisely.

## BFTE-6. Management Recommendations

In [Rec. 09-06] the Commission established a total allowable catch for eastern Atlantic and Mediterranean bluefin tuna at 13,500 t in 2010. Additionally, in [Rec. 09-06] the Commission required that the SCRS provide the scientific basis for the Commission to establish a three-year recovery plan for 2011-2013 with the goal of achieving $\mathrm{B}_{\text {MSY }}$ through 2022 with at least $60 \%$ of probability.

A Kobe II strategy matrix reflecting recovery scenarios of eastern Atlantic and Mediterranean bluefin tuna in accordance with the multiannual recovery plan is given in BFTE-Table 1 and BFTE-Figure 6.

The implementation of recent regulations through [Rec. 09-06, and previous recommendations] has clearly resulted in reductions in catch and fishing mortality rates. But, since the fishery is currently adapting to these new management measures, the Committee is unable to fully understand the implications of the measures on the stock. However, the Committee notes that maintaining catches at the current TAC ( $13,500 \mathrm{t}$ ) under the current management scheme, for 2011-2013, will likely allow the stock to increase during that period and is consistent with the goal of achieving $\mathrm{F}_{\text {MSY }}$ and $\mathrm{B}_{\text {MSY }}$ through 2022 with at least $60 \%$ of probability, given the quantified uncertainties. The 2010 SCRS suggested that the commission might consider more precautionary approach considering the unquantified uncertainties. In 2010, the commission set a TAC at $12,900 \mathrm{t}$ for 2011 and thereafter. Not having completed an updated assessment in 2011 and not having detected any evidence of collapse, the SCRS has no basis to change the 2010 management advice.

| EAST ATLANTIC AND MEDITERRANEAN BLUEFIN TUNA SUMMARY |  |
| :---: | :---: |
| Current (2010) Yield | Reported: 11,294 t |
| Short-term sustainable yield according to Rec.[09-06] | 13,500 t or less |
| Long-term potential yield ${ }^{1}$ | about 50,000 t |
| $\mathrm{SSB}_{2009} / \mathrm{SSB}_{\mathrm{FO} .1}{ }^{2}\left(\mathrm{SSB}_{2009} / \mathrm{SSB}_{\mathrm{FMAX}}\right)^{3}$ |  |
| Medium recruitment scenario (1950-2006) | 0.35 (0.62) |
| Low recruitment scenario (1970s) | 0.51 (0.88) |
| High recruitment scenario (1990s) | 0.19 (0.33) |
| $\mathrm{F}_{2009} / \mathrm{F}_{0.1}{ }^{4}$ |  |
| Reported and inflated catches | 2.9 (1.53) |
| TAC (2009-2011) | 19,950 t-13,500 t-12, 900 t |

## BLUEFIN TUNA - WEST

## BFTW-2. Fishery indicators

The total catch for the West Atlantic peaked at $18,671 \mathrm{t}$ in 1964, mostly due to the Japanese longline fishery for large fish off Brazil and the U.S. purse seine fishery for juvenile fish (BFT-Table 1, BFTW-Figure1). Catches dropped sharply thereafter with the collapse of the bluefin tuna by-catch longline fishery off Brazil in 1967 and decline in purse seine catches, but increased again to average over $5,000 \mathrm{t}$ in the 1970 s due to the expansion of the Japanese longline fleet into the northwest Atlantic and Gulf of Mexico and an increase in purse seine effort targeting larger fish for the sashimi market. The total catch for the West Atlantic including discards has generally been relatively stable since 1982 due to the imposition of quotas. However, since a total catch level of 3,319 t in 2002 (the highest since 1981, with all three major fishing nations indicating higher catches), total catch in the West Atlantic declined steadily to a low of 1,638 t in 2007 and then increased in 2008 and 2009 to 2,000 t and 1,980 t, respectively. The catch in 2010 was $1,830 \mathrm{t}$ (BFTW-Figure 1). The decline through 2007 was primarily due to considerable reductions in catch levels for U.S. fisheries. Since 2002, the Canadian annual catches have been relatively stable at about 500-600 t (733 t in 2006); the 2006 catch was the highest recorded since 1977. The 2010 Canadian catch (including dead discards) was 530 t . Japanese catches have generally fluctuated between 300-500 t, with the exception of $2003(57 \mathrm{t})$, which was low for regulatory reasons, and $2009(162 \mathrm{t})$. Japanese landings for 2010 were 353 t .

The average weight of bluefin tuna taken by the combined fisheries in the West Atlantic were historically low during the 1960s and 1970s (BFTW-Figure 2), for instance showing an average weight of only 33 kg during the 1965-1975 period. However, since 1980 they have been showing a quite stable trend and at a quite high average weight of 93 kg .

The overall number of Japanese vessels engaged in bluefin fishing has declined from more than 100 vessels to currently less than 10 vessels in the West Atlantic. After reaching $2,014 \mathrm{t}$ in 2002 (the highest level since 1979), the catches (landings and discards) of U.S. vessels fishing in the northwest Atlantic (including the Gulf of Mexico) declined precipitously during 2003-2007. The United States did not catch its quota in 2004-2008 with catches of $1,066,848,615,858$ and 922 t , respectively. However, in 2009 the United States fully realized its base quota with total catches (landings including dead discards) of $1,272 \mathrm{t}$ and in 2010 the U.S. catches totaled 925 t and were only slightly below the quota partly owing to a reduction in dead discards.

The indices of abundance used in last year's assessment were updated through 2010 (BFTW-Figure 3). The catch rates of juvenile bluefin tuna in the U.S. rod and reel fishery fluctuate with little apparent long-term trend, but exhibit a pattern that is consistent with the strong year-class estimated for 2003 and show small increases in 2010. The catch rates of adults in the U.S. rod and reel fishery remain low, but increased in 2010 to the highest level since 2002. The catch rates of the Japanese longline fishery north of $30^{\circ} \mathrm{N}$ increased markedly in 2007, decreased in 2008 back to the levels observed in 2005 and 2006 and increased once again in 2009 (the index does not cover 2010 because effort shifted south of $30^{\circ} \mathrm{N}$, but preliminary nominal catch rates in 2010 were similar to 2008) The catch rates from the U.S. Gulf of Mexico longline fishery showed a gradual increasing trend through 2009 (the index has not yet been updated to include 2010 as careful consideration must be given to how to account for the major reductions in effort during that year). The Gulf of Mexico larval survey continues to fluctuate around the low levels observed since the 1980s. The catch rates in the Gulf of St. Lawrence have increased rapidly since 2004 and the catch rates in 2010 were the highest in the time series. The catch rates in southwest Nova Scotia have continued to follow a slightly increasing trend since 2000, with catch rates in 2010 being amongst the highest since the early 1990s.

## BFTW-3. State of the stock

The most recent assessment was conducted in 2010 and included information through 2009 (Anon. 2011c). The most influential change since the 2008 assessment was the use of a new growth curve that assigns fish above 120 cm to older ages than did the previous growth curve. As a result, the base model estimates lower fishing mortality rates and higher biomasses for spawners, but also less potential in terms of the maximum sustainable yield. The trends estimated during the 2010 assessment are consistent with previous analyses in that spawning stock biomass (SSB) declined steadily from 1970 to 1992 and has since fluctuated between $21 \%$ and $29 \%$ of the 1970 level (BFTW-Figure 4). In recent years, however, there appears to have been a gradual increase in SSB from the low of $21 \%$ in 2003 to an estimated $29 \%$ in 2009. The stock has experienced different levels of fishing mortality ( F ) over time, depending on the size of fish targeted by various fleets (BFTW-Figure 4). Fishing mortality on spawners (ages 9 and older) declined markedly after 2003.

Estimates of recruitment were very high in the early 1970s (BFTW-Figure 4), and additional analyses involving longer catch and index series suggest that recruitment was also high during the 1960s. Since 1977, recruitment has varied from year to year without trend with the exception of a strong year-class in 2003. The 2003 year-class is estimated to be the largest since 1974, but not quite as large as those prior to 1974. The 2003 year class is expected to begin to contribute to an increase in spawning biomass after several years. The Committee expressed concern that the year-class estimates subsequent to 2003 while less reliable, are the lowest on record.

A key factor in estimating MSY-related benchmarks is the highest level of recruitment that can be achieved in the long term. Assuming that average recruitment cannot reach the high levels from the early 1970s, recent F (2006-2008) is $70 \%$ of the MSY level and $\mathrm{SSB}_{2009}$ is about $10 \%$ higher than the MSY level (BFTW-Figure 5). Estimates of stock status are more pessimistic if a high recruitment scenario is considered ( $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}=1.9$, $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}=0.15$ ).

One important factor in the recent decline of fishing mortality on large bluefin is that the TAC had not been taken during this time period until 2009, due primarily to a shortfall by the United States fisheries (until 2009). Two plausible explanations for the shortfall were put forward previously by the Committee: (1) that availability of fish to the United States fishery has been abnormally low, and/or (2) the overall size of the population in the Western Atlantic declined substantially from the level of recent years. While there is no overwhelming evidence to favor either explanation over the other, the 2010 base case assessment implicitly favors the first hypothesis (regional changes in availability) by virtue of the estimated increase in SSB. The increase indicated by the U.S. catch rate of large fish is matched by an increase in several other large fish indices (BFTW-Figure 3). Nevertheless, the Committee notes that there remains substantial uncertainty on this issue and more research needs to be done.

The SCRS cautions that the conclusions of the 2010 assessment do not capture the full degree of uncertainty in the assessments and projections. An important factor contributing to uncertainty is mixing between fish of eastern and western origin. Limited analyses were conducted of the two stocks with mixing in 2008, but little new information was available in 2010. Based on earlier work, the estimates of stock status can be expected to vary considerably depending on the type of data used to estimate mixing (conventional tagging or isotope signature samples) and modeling assumptions made. More research needs to be done before mixing models can be used operationally for management advice. Another important source of uncertainty is recruitment, both in terms of recent levels (which are estimated with low precision in the assessment), and potential future levels (the "low" vs. "high" recruitment hypotheses which affect management benchmarks). Improved knowledge of maturity at age will also affect the perception of changes in stock size. Finally, the lack of representative samples of otoliths requires determining the catch at age from length samples, which is imprecise for larger bluefin tuna.

## BFTW-4. Outlook

A medium-term (10-year) outlook evaluation of changes in spawning stock size and yield over the remaining rebuilding period under various management options was conducted in 2010. Future recruitment was assumed to fluctuate around two alternative scenarios: (i) average levels observed for 1976-2006 (85,000 recruits, the low recruitment scenario) and (ii) levels that increase as the stock rebuilds (MSY level of 270,000 recruits, the high recruitment scenario). The Committee has no strong evidence to favor either scenario over the other and notes that both are reasonable (but not extreme) lower and upper bounds on rebuilding potential.

The outlook for bluefin tuna in the West Atlantic with the low recruitment scenario (BFTW-Figure 6) is more optimistic with respect to current stock status than that from the 2008 assessment (owing to the use of improved information on the growth of bluefin tuna). A total catch of $2,500 \mathrm{t}$ is predicted to have at least a $50 \%$ chance of achieving the convention objectives of preventing overfishing and maintaining the stock above the MSY level. The outlook under the high recruitment scenario (BFTW-Figure 6) is more pessimistic than the low recruitment scenario since the rebuilding target would be higher; a total catch of less than $1,250 \mathrm{t}$ is predicted to maintain F below $\mathrm{F}_{\text {MSY }}$, but the stock would not be expected to rebuild by 2019 even with no fishing.

BFTW-Table 1 summarizes the estimated chance that various constant catch policies will allow rebuilding under the high and low recruitment scenarios for the base-case. The low recruitment scenario suggests the stock is above the MSY level with greater than $60 \%$ probability and catches of $2,500 \mathrm{t}$ or lower will maintain it above the MSY level. If the high recruitment scenario is correct, then the western stock will not rebuild by 2019 even with no catch, although catches of $1,100 \mathrm{t}$ or less are predicted to have a $60 \%$ chance to immediately end overfishing and initiate rebuilding.

The Committee reiterates that considerable uncertainties remain for the outlook of the western stock, including the effects of mixing and management measures on the eastern stock.

## BFTW-5. Effects of current regulations

The Committee previously noted that Recommendations 06-06 and 08-04 were expected to result in a rebuilding of the stock towards the convention objective, but also noted that there has not yet been enough time to detect with confidence the population response to the measure. This statement is also true for Recommendation 10-03, which was implemented this year. However, the available fishery indicators (BFTW-Figure 3) continue to suggest the spawning biomass of western bluefin tuna may be slowly rebuilding.

## BFTW-6. Management recommendations

In 1998, the Commission initiated a 20 -year rebuilding plan designed to achieve $\mathrm{B}_{\text {MSY }}$ with at least $50 \%$ probability. In response to recent assessments, in 2008 the Commission recommended a total allowable catch (TAC) of $1,900 \mathrm{t}$ in 2009, $1,800 \mathrm{t}$ in 2010 [Rec. 08-04], and 1,750 t in 2011 [Rec. 10-03].

The latest (2010) assessment indicates similar historical trends in abundance as in previous assessments. The strong 2003 year class has contributed to stock productivity such that biomass has been increasing in recent years.

Future stock productivity, as with prior assessments, is based upon two hypotheses about future recruitment: a 'high recruitment scenario" in which future recruitment has the potential to achieve levels that occurred in the early 1970's and a "low recruitment scenario" in which future recruitment is expected to remain near present levels. Results in previous assessments have shown that long term implications of future biomass are different between the two hypotheses and this research question remains unresolved. However, the 2010 assessment was also based on new information on western bluefin growth rates that has modified the Committee's perception of the ages at which spawning and maturity occur. Maturity schedules remain very uncertain, and, thus, the application of the new information in the 2010 assessment accentuates the differences between the two recruitment hypotheses.

Probabilities of achieving $\mathrm{B}_{\text {MSY }}$ within the Commission rebuilding period were projected for alternative catch levels (BFTW-Table 1, BFTW-Figure 7). The "low recruitment scenario" suggests that biomass is currently sufficient to produce MSY, whereas the "high recruitment scenario" suggests that $\mathrm{B}_{\text {MSY }}$ has a very low probability of being achieved within the rebuilding period. Despite this large uncertainty about the long term future productivity of the stock, under either recruitment scenario current catches ( $1,800 \mathrm{t}$ ) should allow the biomass to continue to increase. Also, catches in excess of $2,500 \mathrm{t}$ will prevent the possibility of the 2003 year class elevating the productivity potential of the stock in the future.

The SCRS notes that the 2010 assessment is the first time that this strong 2003 year-class has been clearly demonstrated, likely as a result of age assignment refinements resulting from the growth curve and additional years of data; more observations from the fishery are required to confirm its relative strength. A further concern is that subsequent year-classes, although even less well estimated, are the lowest observed values in the time series. The Commission may wish to protect the 2003 year class until it reaches maturity and can contribute to spawning. Maintaining TAC at current levels (1,750 t) may offer some protection.

As noted previously by the Committee, both the productivity of western Atlantic bluefin and western Atlantic bluefin fisheries are linked to the eastern Atlantic and Mediterranean stock. Therefore, management actions taken in the eastern Atlantic and Mediterranean are likely to influence the recovery in the western Atlantic, because even small rates of mixing from East to West can have significant effects on the West due to the fact that Eastern plus Mediterranean resource is much larger than that of the West.

Canada discards in 2010 ( 25 t$)$ includes an estimated post-release mortality of 7.5 t from catch and release fisheries and scientific tagging.
China P.R. 2010 catches will change to $38 . \mathrm{t}$ (mistakenly reported as 3.8 t ).

BFTE-Table 1. Probabilities of stock rebuilding at $\mathrm{SSB}_{\mathrm{F} 0.1}$ by years and TAC levels (the probabilities combined the results obtained from the stochastic runs over the 24 scenarios being investigated). The difference in grey colour underlines the catch (TAC) at which the $60 \%$ probability would not be anymore achieved.

BFTW-Figure 1. Historical catches of western bluefin tuna: (a) by gear type and (b) in comparison to TAC levels agreed by the Commission.

BFTW-Figure 2. Historical average weight of bluefin tuna caught by fisheries operating in the western management area.

BFTW-Figure 3. Updated indices of abundance for western bluefin tuna. The dashed portion of the Japanese longline series represents the trend estimated in 2009, which was considered unreliable by the 2010 SCRS. The values for 2010 were considered too preliminary to be shown for the series representing Japanese longline, U.S. longline (Gulf of Mexico), and Canada Gulf of St. Lawrence.

BFTW-Figure 4. Median estimates of spawning biomass (age 9+), fishing mortality on spawners, apical fishing mortality ( F on the most vulnerable age class) and recruitment for the base VPA model. The $80 \%$ confidence intervals are indicated with dotted lines. The recruitment estimates for the last three years of the VPA are considered unreliable and have been replaced by the median levels corresponding to the low recruitment scenario.

BFTW-Figure 5. Estimated status of stock relative to the Convention objectives (MSY) by year (1970 to 2009). The lines give the time series of point estimates for each recruitment scenario and the cloud of symbols depicts the corresponding bootstrap estimates of uncertainty for the most recent year. The large black circle represents the status estimated for 2009.
A) $50 \%$ probability
B) $60 \%$ probability
Low recruitment potential
Low recruitment potential

C) $50 \%$ probability

High Recruitment potential

D) $60 \%$ probability

High recruitment potential

BFTW-Figure 6. Projections of spawning stock biomass (SSB) for the Base Case assessment under low recruitment potential (top panels) and high recruitment potential (bottom panels) and various levels of constant catch. The labels " $50 \%$ " and " $60 \%$ " refer to the probability that the SSB will be greater than or equal to the values indicated by each curve. The curves corresponding to each catch level are arranged sequentially in the same order as the legends. A given catch level is projected to have a $50 \%$ or $60 \%$ probability of meeting the convention objective (SSB greater than or equal to the level that will produce the MSY) in the year that the corresponding curve meets the dashed horizontal line.

BFTW-Figure 7. Kobe II matrices giving the chance that the spawning stock biomass (SSB) will exceed the level that will produce MSY in any given year under various constant catch levels for the Base Case assessment under the low recruitment, high recruitment, and combined scenarios. The red, yellow and green regions represent chances of less than $50 \%, 50-59 \%$ and $60 \%$ or better, respectively.

### 8.6 BLUE MARLIN AND WHITE MARLIN

The most recent assessment for blue marlin was conducted in 2011 through a process that included a data preparatory meeting in May 2010 (Anon. 2011e) and an assessment meeting in April (SCRS/2011/013). The last year of fishery data used in the assessment was 2009.

## BUM/WHM-1. Biology

The central and northern Caribbean Sea and northern Bahamas have historically been known as the primary spawning area for blue marlin in the western North Atlantic. Recent reports show that blue marlin spawning can also occur north of the Bahamas in an offshore area near Bermuda at about $32^{\circ}-34^{\circ}$ North. Ovaries of female blue marlin caught by artisanal vessel in Côte d'Ivoire show evidence of pre-spawning and post-spawning, but not of spawning. In this area females are more abundant than males ( $4: 1$ female/male ratio). Coastal areas off West Africa have strong seasonal upwelling, and may be feeding areas for blue marlin.

Previous reports have mentioned spawning of white marlin off southeast Brazil ( $25^{\circ}$ to $26^{\circ} \mathrm{S}$ and $45^{\circ}$ to $45^{\circ} \mathrm{W}$ ) in the same area where blue marlin spawn. In this area blue marlin spawn from April to June and white marlin spawn from December to March. In the northwest Atlantic white marlin have been reported spawning in the Gulf of Mexico in June. Recent reports confirm that white marlin also spawns offshore and north of the Antilles ( $19^{\circ}$ to $23^{\circ} \mathrm{N}$ and $60^{\circ}$ to $70^{\circ} \mathrm{W}$ ) between April and July.

Atlantic blue marlin inhabit the upper parts of the open ocean. Although they spend much of the time on the upper mixed layer they dive regularly to maximum depths of around 300 m , with some vertical excursions down to 800 m . They do not confine themselves to a narrow range of temperatures but most tend to be found in waters warmer than $17^{\circ} \mathrm{C}$. The distributions of times at depth are significantly different between day and night. At night, the fish spent most of their time at or very close to the surface. During daylight hours, they are typically below the surface, often at 40 to $100+\mathrm{m}$. These patterns, however, can be highly variable between individuals and also vary depending on the temperature and dissolved oxygen of the surface mixed layer. This variability in the use of habitat by marlins indicates that simplistic assumptions about habitat usage made during the standardization of CPUE data may be inappropriate.

All biological material sampled to date from white marlin, prior to the confirmation of the existence of roundscale spearfish (T. georgii) in 2006, contains unknown mixture of the roundscale spearfish and white marlin. Therefore reproductive parameters, growth curves and other biological studies previously thought to describe white marlin may not exclusively represent this species.

## BUM/WHM-2. Fishery indicators

It has now been confirmed that white marlin landings reported to ICCAT include roundscale spearfish in significant numbers, so that historical statistics of white marlin include a mixture of both species. Studies of white marlin/roundscale spearfish ratios have been conducted, with overall estimated ratios between 23-27\%. Previously, these were thought to represent only white marlin. In some areas, however, only one species is present in these samples.

The decadal geographic distribution of the catches is given in BUM/WHM-Figure 1. The Committee used Task I catches as the basis for the estimation of total removals (BUM/WHM-Figure 2). Total removals for the period 1990-2009 were obtained during the 2011 Blue Marlin Stock Assessment Session and the White Marlin Data Preparatory Meeting (SCRS/2011/013) by modifying Task I values with the addition of blue marlin and white marlin that the Committee estimated from catches reported as billfish unclassified. Additionally the reporting gaps were filled with estimated values for some fleets.

During the 2011 blue marlin assessment it was noted that catches continued to decline through 2009, while catches of white marlin seemed to be stabilizing. Over the last 20 years, Antillean artisanal fleets have increased the use of Moored Fish Aggregating Devices (MFADs) to capture pelagic fish. Catches of blue marlin caught around MFADs are known to be significant and increasing in some areas, however reports to ICCAT on these catches are incomplete. Even though catches from the Antillean artisanal fleets were included in the stock assessment, additional documentation of past and present Task I catches from these fisheries is required. Recent reports from purse seine fleets in West Africa suggest that blue marlin are more commonly caught with tuna schools associated with FADs than with free tuna schools. Task I catches of blue marlin (BUM/WHM-Table 1) in 2010 were $3,160 \mathrm{t}$, compared to $3,240 \mathrm{t}$ reported for 2009. Task I catches of white marlin in 2009 and 2010
were 644 t and 372 t , respectively (BUM/WHM-Table 2). Task I catches of white marlin and blue marlin for 2010 are preliminary. Due to the work conducted by the Committee and improved reporting by CPCs the amount of unclassified billfish in the Task I table has been minimized.

A number of relative abundance indices were estimated during the blue marlin 2011 assessment and white marlin data preparatory meeting. However, given the apparent shift in landings from industrial to non-industrial fleets in recent times, it is imperative that CPUE indices are developed for all fleets that have substantial landings.

During the 2011 assessment, an estimated standardized combined CPUE index for blue marlin showed a sharp decline during the period 1960-1975, followed by a period of stabilization from about 1976 to 1995 and further decline thereafter (BUM/WHM-Figure 3).

A series of indices of abundance for white marlin were presented and discussed during the 2011 meetings. In general, the indices showed no discerning trend during the latter part of the time series examined (BUM/WHMFigure 4).

## BUM/WHM-3. State of the stocks

## Blue marlin

Unlike the partial assessment of 2006 assessment, the Committee conducted a full assessment in 2011, which included estimations of management benchmarks. The results of the 2011 assessment indicated that the stock remains overfished and undergoing overfishing (BUM/WHM-Figure 5). This is in contrast to the results of the 2006 assessment which indicated that even though the stock was likely overfished, the declining trend had partially stabilized. Current status of the blue marlin stock is presented in BUM-WHM Figure 6. However, the Committee recognizes the high uncertainty with regard to data and the productivity of the stock.

## White marlin

No new information on stock status has been provided since the 2006 assessment (Anon. 2007). The biomass for 2000-2004 most likely remained well below the $\mathrm{B}_{\text {MSY }}$ estimated in the 2002 assessment (Anon. 2003). During the last assessment, it was estimated that F 2004 was probably smaller than $\mathrm{F}_{\text {replacement }}$ and also probably larger than the $\mathrm{F}_{\text {MSY }}$ estimated in the 2002 assessment. Over the period 2001-2004, combined longline indices and some individual fleet indices suggest that the decline has been at least partially reversed, while other individual fleet indices suggest that abundance has continued to decline. The next stock assessment (2012) may confirm if these recent apparent changes in trend have continued. During the 2011 data preparatory meeting, the Committee reviewed available information and concluded that the separation of historical landings of white marlin and roundscale spearfish can not be conducted. In addition, all historical indices of abundance of white marlin most likely included roundscale spearfish.

## BUM/WHM-4. Outlook

Although uncertain, the results of the 2011 stock assessement indicated that if the recent catch levels of blue marlin ( $3,240 \mathrm{t}$ in 2009) are not substantially reduced, the stock will continue to decline further (BUM/WHMFigure 7). The current management plan does not have the potential of recovering the blue marlin stock to the $\mathrm{B}_{\text {MSY }}$ level.

No new information on the recovery/outlook for white marlin has been provided since the 2006 assessment (Anon. 2007). Based on the results of the 2006 stock assessment, the Committee noted that the Commission's current management plan has the potential of recovering the white marlin stock. However, this conclusion requires further confirmation based on the 2012 white marlin stock assessment.

Most recent catch per unit effort data for white marlin lacked any discernable trend.
The presence of unknown quantities of roundscale spearfish in the biological parameters, historical landings and relative abundance estimates of white marlin increase the uncertainty for the stock status and outlook for this species.

## BUM/WHM-5. Effect of current regulations

Recommendations [Rec. 00-13], [Rec. 01-10] and [Rec. 02-13] placed additional catch restrictions for blue marlin and white marlin. The latter established that "the annual amount of blue marlin that can be harvested by pelagic longline and purse seine vessels and retained for landing must be no more than $33 \%$ for white marlin and $50 \%$ for blue marlin of the 1996 or 1999 landing levels, whichever is greater". That recommendation established that: "All blue marlin and white marlin brought to pelagic longline and purse seine vessels alive shall be released in a manner that maximizes their survival. The provision of this paragraph does not apply to marlins that are dead when brought along the side of the vessel and that are not sold or entered into commerce". The Committee estimated the catch of pelagic longline vessels for a subset of fleets that the Committee thought would be expected to be affected by Recommendations [Rec. 00-13] and [Rec. 02-13]. Catches of these fleets represent $97 \%$ of all longline caught blue marlin, and $93 \%$ of all longline caught white marlin for the period 1990-2007. Catches of both species have declined since 1996-99, the period selected as the reference period by the recommendations. Since 2002, the year of implementation of the last of these two recommendations, the catch of blue marlin has been below the $50 \%$ value recommended by the Commission. Specifically, the 2011 longline landings were $51 \%$ of the baseline established by the Commission. Similarly, the catch of white marlin since 2002 has been at about the $33 \%$ value recommended by the Commission. This analysis represents only longline caught marlin even though the recommendations referred to the combined catch of pelagic longline and purse seine, because the catch estimates of billfish bycatch from purse seine vessels are more uncertain than those from longline. Over the period considered, purse seine caught marlin represent $2 \%$ of the total catch reported by the combination of purse seine and pelagic longline.

The Committee notes that the management plan developed by the Commission was based on the fact that at that time most blue marlin and white marlin originated from industrial fisheries. Since then, the Committee noted a significant increase in the contribution from non-industrial fisheries to the total blue marlin and white marlin harvest and that these fisheries are not fully accounted for in the current management plan.

Some fisheries/fleets are using circle hooks, which can minimize deep hooking and increase the survival of marlins hooked on longlines and recreational gear. More countries have started reporting data on live releases in 2006. Additional information has come about, for some fleets, regarding the potential for modifying gears to reduce the by-catch and increase the survival of marlins. Such studies have also provided information on the rates of live releases for those fleets. However there is not enough information on the proportion of fish being released alive for all fleets, to evaluate the effectiveness of the ICCAT recommendation relating to the live release of marlins.

## BUM/WHM-6. Management recommendations

The current blue marlin stock assessment, considering all the uncertainties in the assessment, indicates that the stock is below $\mathrm{B}_{\text {MSY }}$ and that fishing mortality is above $\mathrm{F}_{\text {MSY }}$ (2009). Unless the recent catch levels ( $3,240 \mathrm{t}$, 2009) are substantially reduced, the stock will likely continue to decline. The Commission should adopt a rebuilding plan for the stock of Atlantic blue marlin.

The Commission should implement management measures to immediately reduce fishing mortality on blue marlin stock by adopting a TAC that allow the stock to increase (2,000 t or less, including dead discards; BUM/WHM-Table 2):

1. To facilitate the implementation of the TAC, the commission may consider the adoption of measures such as, but not limited to:
a) Total prohibition of landings of blue marlin from pelagic longline and purse seine fisheries to improve the effectiveness of current management measures.
b) Encouraging the use of alternative gear configurations that reduce the likelihood of deep hooking therefore increasing the post-release survival (for example, circle hooks) and/or reduce catchability (e.g., reducing the number of shallowhooks in a longline set, etc).
c) Implementation of time-area closures.
d) Reduce fishing mortality of blue marlin from non-industrial fisheries.
2. Noting the misidentification problems between white marlin and spearfishes, the Group recommended that management recommendations combine these species as a mixed stock until more accurate species identification and differentiation of species catches are available.
3. The Commission should encourage the reporting of catches of white marlin and roundscale spearfish separated.

|  | ATLANTIC BLUE MARLIN SUMMARY |
| :--- | :---: |
|  | BUM |
| Maximum Sustainable Yield | $2,837 \mathrm{t}(2,343-3,331 \mathrm{t})^{1}$ |
| Current $(2010)$ Yield | $3,160 \mathrm{t}^{2}$ |
| Relative Biomass | $0.67(0.53-0.81)^{1}$ |
| $\left(\mathrm{SSB}_{2009} / \mathrm{SSB}_{\text {MSY }}\right)$ | $1.63(1.11-2.16)^{1}$ |
| Relative Fishing Mortality $^{\left(\mathrm{F}_{2009} / \mathrm{F}_{\text {MSY }}\right)}$ |  |

Conservation and Management Measure in Effect

Recommendation [Rec. 06-09]. The annual amount of blue marlin that can be harvested by pelagic longline and purse seine vessels and retained for landing must be no more than 33\% for white marlin and $50 \%$ for blue marlin of the 1996 or 1999 landing levels, whichever is greater.
${ }^{1}$ Stock Synthesis version 3.2.0.b model results. Values correspond to median estimates, $95 \%$ confidence interval values are provided in parenthesis.
${ }^{2} 2010$ yield should be considered provisional. 2009 yield corresponded to $3,240 \mathrm{t}$. The 2009 yield used in the 2011 assessment was $3,341 \mathrm{t}$.

BUM-WHM Figure 1b. Geographic distribution of mean white marlin catch by major gears and decade. The symbols for the 1950s information (top left) are scaled to the maximum catch observed during the 1950s, whereas the remaining plots are scaled to the maximum catch observed from 1960 to 2009.

BUM-WHM-Figure 2. Total catch of blue marlin and white marlin reported in Task I.

BUM-WHM-Figure 3. Blue marlin standardized combined CPUE indices estimated using equal weighting for all CPUE series (EQW), weighting the CPUE series by area (ARW) and by catch (CAW).

BUM-WHM-Figure 4. White marlin indices of abundance presented during the meeting. For graphing purposes the indices were scaled to their respective mean value for the period 1990-2010.

BUM-WHM Figure 5. Trends of $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ and $\mathrm{SSB} / \mathrm{SSB}_{\text {MSY }}$ ratios for blue marlin from the base model (SS3). Solid lines represent median from MCMC runs, and broken lines the $10 \%$ and $90 \%$ percentiles, respectively.

BUM-WHM Figure 6. Phase plot for blue marlin from the base model in final year model assessment (2009). Individual points represent MCMC iterations, large diamond the median of the series. Blue circles with line represent the historic trend of the median $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ vs $\mathrm{SSB} / \mathrm{SSB}_{\mathrm{MSY}}$ 1965-2008.

BUM-WHM Figure 7. Trends of $\mathrm{SSB} / \mathrm{SSB}_{\text {MSy }}$ ratios under different scenarios of constant catch projections (TAC tons) for blue marlin from the base model. Projections start in 2010, for 2010/11 it was assumed a catch of 3,341 t.

### 8.7 SAI - SAILFISH

Sailfish (Istiophorus platypterus) has a pan-tropical distribution. ICCAT has established, based on life history information on migration rates and geographic distribution of catch, that there are two management units for Atlantic sailfish, eastern and western (SAI-Figure 1). The first successful assessment that estimated reference points for eastern and western sailfish stocks was conducted in 2009 (Anon. 2010a).

## SAI-1. Biology

Larval sailfish are voracious feeders initially feeding on crustaceans from the zooplankton but soon switching to a diet of fish larvae. Temperature preferences for adult sailfish appear to be in the range of $25-28^{\circ} \mathrm{C}$. A study undertaken in the Strait of Florida and the southern Gulf of Mexico indicated that habitat preferences from satellite tagged sailfish were primarily within the upper $20 \sim 50 \mathrm{~m}$ of the water column. The tag data also indicated common short-term movements to depths in excess of 100 m , with some dives as deep as 350 m . Sailfish is the most coastal of all billfish species and conventional tagging data suggest that they move shorter distances than the other billfish (SAI-Figure 2). Sailfish grow rapidly and reach a maximum size of 160 cm for males and 220 cm for females, with females reaching maturity at 155 cm . Sailfish reach a maximum age of at least 17 years.

Sailfish spawn over a wide area and year around. In the North, evidence of spawning has been detected in the Straits of Florida, and off the Venezuelan, Guyanese and Surinamese coasts. In the southwest Atlantic, spawning occurs off the southern coast of Brazil between $20^{\circ}$ and $27^{\circ}$, and in the east Atlantic, off Senegal and Côte d'Ivoire. Timing of spawning can differ between regions. From the Florida Straits to the areas off Guyana sailfish spawn in the second semester of the year, whist in the southwestern Atlantic and the tropical eastern Atlantic they spawn late and early in the year.

## SAI-2. Description of the fisheries

Sailfish are targeted by coastal artisanal and recreational fleets and, to a less extent, are caught as by-catch in longline and purse seine fisheries (SAI-Figure 1). Historically, catches of sailfish were reported together with spearfish by many longline fleets. In 2009 these catches were separated by the Species Group (SAI-Table 1). Historical catches of unclassified billfish continue to be reported to the Committee making the estimation of sailfish catch difficult. Catch reports from countries that have historically been known to land sailfish continue to suffer from gaps and there is increasing ad-hoc evidence of un-reported landings in some other countries. These considerations provide support to the idea that the historical catch of sailfish has been under-reported, especially in recent times where more and more fleets encounter sailfish as by-catch or target them.

Reports to ICCAT estimate that the Task I catch for 2010 was $2,771 \mathrm{t}$ and 625 t for the east and west stocks, respectively (SAI-Figure 3). Task I catches of sailfish for 2010 are preliminary because they do not include reports from all fleets.

## SAI-3. State of the stocks

ICCAT recognizes the presence of two stocks of sailfish in the Atlantic, the eastern and western stocks. There is increasing evidence that an alternative stock structure with a north western stock and a south/eastern stock should be considered. Assessments of stocks based on the alternative stock structure option have not been done to date, however, conducting them should be a priority for future assessments.

In 2009 ICCAT conducted a full assessment of both Atlantic sailfish stocks (Anon. 2010a) through a range of production models and by using different combinations of relative abundance indices (SAI-Figure 4). It is clear that there remains considerable uncertainty regarding the stock status of these two stocks, however, many assessment model results present evidence of overfishing and evidence that the stocks are overfished, more so in the east than in the west. Although some of the results suggest a healthy stock in the west, few suggest the same for the east. The eastern stock is also assessed to be more productive than the western stock, and probably able to provide a greater MSY. The eastern stock is likely to be suffering stronger overfishing and most probably has been reduced further below the level that would produce the MSY than the western stock. Reference points obtained with other methods reach similar conclusions.

Examination of recent trends in abundance suggests that both the eastern and western stocks suffered their greatest declines in abundance prior to 1990. Since 1990, trends in relative abundance conflict between different
indices, with some indices suggesting declines, other increases and others not showing a trend (SAI-Figure 4). Examination of available length frequencies for a range of fleets show that average length and length distributions do not show clear trends during the period where there are observations. A similar result was obtained in the past for marlins. Although it is possible that, like in the case of the marlins, this reflects the fact that mean length is not a good indicator of fishing pressure for billfish it could also reflect a pattern of high fishing pressure over the period of observation.

## SAI-4. Outlook

Both the eastern and western stocks of sailfish may have been reduced to stock sizes below $\mathrm{B}_{\text {MSy }}$. There is considerable uncertainty on the level of reduction, particularly for the west, as various production model fits indicated the biomass ratio $\mathrm{B}_{2007} / \mathrm{B}_{\mathrm{MSY}}$ both above and below 1.0. The results for the eastern stock were more pessimistic than those for the western stock in that more of the results indicated recent stock biomass below $\mathrm{B}_{\mathrm{MSY}}$. Therefore there is particular concern over the outlook for the eastern stock.

## SAI-5. Effect of current regulations

No ICCAT regulations for sailfish are in effect, however, some countries have established domestic regulations to limit the catch of sailfish. Among these regulations are: requirement of releasing all billfish from longline vessels, minimum size restrictions, circle hooks and catch and release strategies in sport fisheries

## SAI-6. Management recommendations

The Committee recommends that catches for the eastern stock should be reduced from current levels. It should be noted, however, that artisanal fishermen harvest a large part of the sailfish catch along the African coast.

The Committee recommends that catches of the western stock of sailfish should not exceed current levels. Any reduction in catch in the West Atlantic is likely to help stock re-growth and reduce the likelihood that the stock is overfished. It should be noted, however, that artisanal fishermen harvest a large part of the sailfish catch of the western sailfish stock.

The Committee is concerned about the incomplete reporting of sailfish catches, particularly for the most recent years, because it increases uncertainty in stock status determination. The Committee recommends all countries landing or having dead discards of sailfish, report these data to the ICCAT Secretariat.

## ATLANTIC SAILFISH SUMMARY

|  | West Atlantic | East Atlantic |
| :--- | :--- | :--- |
| Maximum Sustainable Yield (MSY) | $600-1,100^{1} \mathrm{t}$ | $1,250-1,950^{1} \mathrm{t}$ |
| 2010 Catches (Provisional) | 625 t | $2,771^{3} \mathrm{t}$ |
| $\mathrm{B}_{2007} / \mathrm{B}_{\text {MSY }}$ | Possibly $<1.0$ | Likely $<1.0$ |
| $\mathrm{~F}_{2007} / \mathrm{F}_{\text {MSY }}$ | Possibly $>1.0$ | Likely $>1.0$ |
| 2008 Replacement Yield | not estimated | not estimated |

SAI-Figure 1. Geographic distribution of mean sailfish catch by major gears and by decade. The dark line denotes the separation between stocks. The symbols for the 1950s information (top left) are scaled to the maximum catch observed during the 1950s, whereas the remaining plots are scaled to the maximum catch observed from 1960 to 2009.

SAI-Figure 2. Conventional tag returns for Atlantic sailfish. Lines join the locations of release and recapture.

SAI-Figure 3. Task I catches of sailfish for each of the two Atlantic stocks, East and West.

SAI-Figure 4. Relative abundance indices obtained by standardizing CPUE data for various fleets. All indices were scaled to the mean of each series prior to graphing.

### 8.8 SWO-ATL-ATLANTIC SWORDFISH

The last assessment for Atlantic swordfish was conducted in 2009 (Anon. 2010c). Other information relevant to Atlantic swordfish is presented in the Report of the Sub-Committee on Statistics, included as Appendix 7 to this SCRS Report, and recommendations pertinent to Atlantic swordfish are presented in Section 17.

## SWO-ATL-1. Biology

Swordfish (Xiphias gladius) are members of the family Xiphiidae and are in the suborder Scombroidei. They can reach a maximum weight in excess of 500 kg . They are distributed widely in the Atlantic Ocean and Mediterranean Sea. In the ICCAT Convention area, the management units of swordfish for assessment purposes are a separate Mediterranean group, and North and South Atlantic groups separated at $5^{\circ} \mathrm{N}$. This stock separation is supported by recent genetic analyses. However, the precise boundaries between stocks are uncertain, and mixing is expected to be highest at the boundary in the tropical zone. Swordfish feed on a wide variety of prey including groundfish, pelagic fish, deep-water fish, and invertebrates. They are believed to feed throughout the water column, and from recent electronic tagging studies, undertake extensive diel vertical migrations. SCRS 2011/134 provided new information on the food habits of South Atlantic swordfish. A Bayesian analysis of stomach contents of swordfish caught off the southern coast of Brazil indicated that the diet consisted primarily of cephalopods, and secondarily of fish. The authors noted, however, that the diet of swordfish is known to vary considerably, both geographically and seasonally.

Swordfish mostly spawn in the western warm tropical and subtropical waters throughout the year, although seasonality has been reported in some of these areas. They are found in the colder temperate waters during summer and fall months. Young swordfish grow very rapidly, reaching about 140 cm LJFL (lower-jaw fork length) by age three, but grow slowly thereafter. Females grow faster than males and reach a larger maximum size. Tagging studies have shown that some swordfish can live up to 15 years. Swordfish are difficult to age, but about $50 \%$ of females were considered to be mature by age five, at a length of about 180 cm . However, the most recent information indicates a smaller length and age at maturity.

## SWO-ATL-2. Fishery indicators

Due to the broad geographical distribution of Atlantic swordfish (SWO ATL-Figure 1) in coastal and off-shore areas (mostly ranging from $50^{\circ} \mathrm{N}$ to $45^{\circ} \mathrm{S}$ ), this species is available to a large number of fishing countries (SWO ATL-Figure 2). Directed longline fisheries from Canada, EU-Spain, and the United States have operated since the late 1950 s or early 1960s, and harpoon fisheries have existed at least since the late 1800s. Other directed swordfish fisheries include fleets from Brazil, Morocco, Namibia, EU-Portugal, South Africa, Uruguay, and Venezuela. The primary by-catch or opportunistic fisheries that take swordfish are tuna fleets from Chinese Taipei, Japan, Korea and EU-France. The tuna longline fishery started in 1956 and has operated throughout the Atlantic since then, with substantial catches of swordfish that are produced as a by-catch of tuna fisheries. The largest proportion of the Atlantic catches is made using surface-drifting longline. However, many additional gears are used, including traditional gillnets off the coast of western Africa.

## Total Atlantic

The total Atlantic estimated catch (landings plus dead discards) of swordfish (North and South, including reported dead discards) in $2010(24,720 t)$ is close to the reported catch in $2009(24,761 \mathrm{t})$. As a small number of countries have not yet reported their 2010 catches and because of unknown unreported catches, this value should be considered provisional and subject to further revision.

In an effort to quantify possible unreported catches in the Convention area during the 2009 stock assessment, the ICCAT Statistical Document data base was examined. The use of this information was complicated because of the lack of conversions factors available for products such as loin, fillet, and gilled/gutted swordfish. The comparison between the swordfish Statistical Document System (s.SDS) data from 2003 through 2007 and the reported Task I by flag indicates that Task I catches might not represent the total landed catch of Convention area swordfish, although the extent to which this occurs was highly uncertain. The largest discrepancy between the data sources is for flags with an unknown area of capture, and amounts to nearly 21,000 t over the 2003-2007 time period. Considering only the s.SDS data classified as coming from the Convention area, the discrepancy amounts to an estimate of less than $1,000 \mathrm{t}$ over the time period. The comparison implies that international trade of Convention Area landed swordfish might represent less than $13 \%$ of the landed catch recorded in Task I and that a surprisingly low number of Contracting Parties engage in export of Convention area swordfish.

## North Atlantic

For the past decade, the North Atlantic estimated catch (landings plus dead discards) has averaged about 11,523 t per year (SWO-ATL-Table 1 and SWO-ATL-Figure 3). The catch in 2010 (12,154 t) represents a $40 \%$ decrease since the 1987 peak in North Atlantic landings (20,236 t). These reduced landings have been attributed to ICCAT regulatory recommendations and shifts in fleet distributions, including the movement of some vessels in certain years to the South Atlantic or out of the Atlantic. In addition, some fleets, including at least the United States, EU-Spain, EU-Portugal and Canada, have changed operating procedures to opportunistically target tuna and/or sharks, taking advantage of market conditions and higher relative catch rates of these species previously considered as by-catch in some fleets. Recently, socio-economic factors may have also contributed to the decline in catch.

Trends in nominal catch rates by fleets contributing to the production model are shown in SWO-ATL-Figure 4. Most of the series have an increasing trend since the late 1990s, but the U.S. catch rates remained relatively flat. There have been some recent changes in United States regulations that may have impacted catch rates, but these effects remain unknown.

The 2011 Swordfish Species Group reviewed new information from Canada, which provided updated age and sex-specific nominal catch rate series for its pelagic longline fishery (SCRS/2011/186) for the period from 2002 to 2011. The trend in CPUE indicates that relative abundance has continued to increase since the series low in 2006 and is near the historical high observed in 1990. Reports from the USA also indicate relatively high recent catch rates.

The most frequently occurring ages in the catch include ages 2 and 3 (SWO-ATL-Figure 5). There were reports of increasing average size of the catch in USA fisheries.

## South Atlantic

The historical trend of catch (landings plus dead discards) can be divided in two periods: before and after 1980. The first one is characterized by relatively low catches, generally less than $5,000 \mathrm{t}$ (with an average value of $2,300 \mathrm{t}$ ). After 1980, landings increased continuously up to a peak of $21,930 \mathrm{t}$ in 1995 , levels that are comparable to the peak of North Atlantic harvest (20,236 t). This increase of landings was, in part, due to progressive shifts of fishing effort to the South Atlantic, primarily from the North Atlantic, as well as other waters. Expansion of fishing activities by southern coastal countries, such as Brazil and Uruguay, also contributed to this increase in catches. The reduction in catch following the peak in 1995 resulted from regulations and partly due to a shift to other oceans and target species. In 2010, the 12,566 t reported catches were about $43 \%$ lower than the 1995 reported level (SWO-ATL-Figure 3). The SCRS received reports from Brazil and Uruguay that those CPCs have reduced their fishing effort directed towards swordfish in recent years.

In 2010, the SCRS noted that there was a considerable decline in the magnitude of the catch by Namibia in 2009 compared with 2008 (25 and 518 t , respectively) that appeared inconsistent with recent developments in capacity. In particular, the 2008 value appears to be low, compared with information from other sources such as compliance tables. While Namibian authorities were contacted with a request for an explanation for this apparent anomaly, a response has not yet been received

As observed in the 2006 assessment, the CPUE trend from targeted and non-targeted fisheries show different trends and high variability which indicates that at least some are not depicting trends in the abundances of the stock (SWO-ATL-Figure 6). It was noted that there was little overlap in fishing area and strategies between the by-catch and targeted fleets used for estimating CPUE pattern, and therefore the by-catch and targeted fisheries CPUE trends could be tracking different components of the population.

## Discards

Since 1991, several fleets have reported dead discards (see SWO-ATL-Table 1). The volume of Atlantic-wide reported discards since then has ranged from 151 t to $1,139 \mathrm{t}$ per year. Reported annual dead discards (in tonnes) have been declining in recent years.

## SWO-ATL-3. State of the stocks

## North Atlantic

Results from the base case production model are shown in SWO-ATL-Figure 7. The estimated relative biomass trend shows a consistent increase since 2000. The current results indicate that the stock is at or above $\mathrm{B}_{\text {MSY }}$. The relative trend in fishing mortality shows that the level of fishing peak in 1995, followed by a decrease until 2002, followed by small increase in the 2003-2005 period and downward trend since then. Fishing mortality has been below $\mathrm{F}_{\text {MSY }}$ since 2005. The results suggest that there is greater than $50 \%$ probability that the stock is at or above $\mathrm{B}_{\mathrm{MSY}}$, and thus the Commission's rebuilding objective [Rec. 99-02] has been achieved (SWO-ATL-Figure 8). However, it is important to note that since 2003 the catches have been below the TAC's greatly increasing the chances for a fast recovery. Overall, the stock was estimated to be somewhat less productive than the previous assessment, with the intrinsic rate of increase, $r$, estimated at 0.44 compared to 0.49 in 2006.

Other analyses conducted by the SCRS (Bayesian surplus production modeling, and Virtual Population Analyses) generally support the results described for the base case surplus production model above.

## South Atlantic

The results of the base case production model indicated that there were conflicting signals for several of the indices used. The model estimated overall index was relatively stable until the early 1980s when it started declining until the late 1990s and it reversed that trend about 2003. Estimated relative fishing mortality ( $\mathrm{F}_{2008} / \mathrm{F}_{\mathrm{MSY}}$ ) was 0.75 indicating that the stock is not being overexploited. Estimated relative biomass ( $\mathrm{B}_{2009} / \mathrm{B}_{\mathrm{MSY}}$ ) was 1.04 (SWO-ATL-Figure 9), indicating that the stock was not overexploited.

Because of the high level of uncertainty associated with the south Atlantic production models results, the SCRS conducted catch-only modeling analysis, including two explorations using different assumptions concerning the intrinsic rate of population increase. The distribution for MSY was skewed for both runs (SWO-ATL-Figure 10). The median of MSY estimated for Run 1 was $18,130 \mathrm{t}$ and for Run 2 was $17,934 \mathrm{t}$. SWO-ATL-Figure 11 summarizes recent stock status, as determined from the catch-only model.

## SWO-ATL-4. Outlook

## North Atlantic

The base production model was projected to the year 2018 under constant TAC scenarios of 10, 11, 12, 13, 14 and 15 thousand tones. Catch in year 2009 was assumed to be the average of the last three years (2006-08) ( $11,515 \mathrm{t}$ ). The actual reported landings in 2009 were $12,655 \mathrm{t}$. Median trajectories for biomass and fishing mortality rate for all of the future TAC scenarios are plotted in SWO-ATL-Figure 12.

Future TACs above MSY are projected to result in $50 \%$ or lower probabilities of the stock biomass remaining above $\mathrm{B}_{\text {MSY }}$ over the next decade (SWO-ATL-Figure 13) as the resulting probability of F exceeding $\mathrm{F}_{\text {MSY }}$ for these scenarios would trend above $50 \%$ over time. A TAC of 13,000 t would provide approximately a $75 \%$ probability of maintaining the stock at a level consistent with the Convention objective over the next decade.

## South Atlantic

Projections for the base case production model were performed for catch levels from $10,000 \mathrm{t}$ to $16,000 \mathrm{t}$ by increments of $1,000 \mathrm{t}$ for 2010-2020. For 2009, all projection scenarios assumed a catch equal to the average catch for 2006-2008 (13,658 t). SWO-ATL-Figure 14 shows the results of the projections. Because the SCRS considers that the production model estimated benchmarks are poorly estimated, the projections are shown as biomass changes rather than relative biomass. In general, catches of $14,000 \mathrm{t}$ or less will result in increases in the biomass of the stock; catches on the order of 15,000 will maintain the biomass of the stock at approximately stable levels during the period projected. Catches on the order of $16,000 \mathrm{t}$ or more will result in biomass decrease. The current TAC is $15,000 \mathrm{t}$.

For the catch only model projections, constant catch scenarios were evaluated ranging from 10,000 to $17,000 \mathrm{t}$, incremented by $1,000 \mathrm{t}$ for a period of 10 years. For 2009, all projection scenarios assumed a catch equal to the average catch for 2006-2008 (13,658 t). In general, catches of $15,000 \mathrm{t}$ will result in the biomasses being higher than $\mathrm{B}_{\mathrm{MSY}} 80 \%$ of the time. SWO-ATL-Figure 15 summarizes the probability of $\mathrm{B}>\mathrm{B}_{\text {MSY }}$ and $\mathrm{F}<\mathrm{F}_{\text {MSY }}$ for the
constant catch scenarios indicated over time. Catches on the order of 17,000 will result in a probability of 0.67 of the biomass being above $\mathrm{B}_{\text {MSY }}$ in ten years.

## SWO-ATL-5. Effects of current regulations

In 2006, the Committee provided information on the effectiveness of existing minimum size regulations. New catch regulations were implemented on the basis of Rec. 06-02, which entered into effect in 2007 (Rec. 08-02 extended the provisions of Rec. 06-02 to include 2009). Rec. 09-02 came into effect in 2010 and extended most of the provisions of Rec. 06-02 for one year only. Rec. 10-02 came into effect in 2011, and again extended those provisions for one year only, but with a slight reduction in total allowable catch (TAC).

For the South Atlantic, the most recent recommendation can be found in Rec. 09-03, which establishes a three year management plan for that stock.

## Catch limits

The total allowable catch in the North Atlantic during the 2007 to 2009 period was 14,000 t per year. The reported catch during that period averaged $11,969 \mathrm{t}$ and did not exceed the TAC in any year. In 2010, the TAC was reduced to $13,700 \mathrm{t}$, compared with catches of $12,154 \mathrm{t}$. Reports for 2010 are considered provisional and subject to change.

The total allowable catch in the South Atlantic for the years 2007 through 2009 was $17,000 \mathrm{t}$. The reported catch during that period averaged $13,482 \mathrm{t}$, and did not exceed the TAC in any year. In 2010, the TAC was reduced to $15,000 \mathrm{t}$, and the catch in that year was $12,566 \mathrm{t}$. Reports for 2010 are considered provisional and subject to change.

## Minimum size limits

There are two minimum size options that are applied to the entire Atlantic: 125 cm LJFL with a $15 \%$ tolerance, or 119 cm LJFL with zero tolerance and evaluation of the discards.

For the 2006-2008 period, the estimate of the percentage of swordfish reported landed (throughout the Atlantic) less than 125 cm LJFL was about $24 \%$ (in number) overall for all nations fishing in the Atlantic ( $28 \%$ in the northern stock and $20 \%$ in southern stock). If this calculation is made using reported landings plus estimated dead discards, then the percentage less than 125 cm LJFL would be of the same order given the relatively small amount of discards reported. These estimates are based on the overall catch at size, which have high levels of substitutions for a significant portion of the total catch.

## Other implications

The Committee is concerned that in some cases national regulations have resulted in the unreported discarding of swordfish caught in the North stock and, to a certain extent, could have influenced similar behavior of the fleet that fishes the South Atlantic swordfish stock. The Committee considers that these regulations may have had a detrimental effect on the availability and consistency of scientific data on catches, sizes and CPUE indices of the Atlantic fleet. The Committee expressed its serious concern over this limitation on data for future assessments.

## SWO-ATL-6. Management recommendations

## North Atlantic

The Committee continues to note that the allowable country-specific catch levels agreed in [Recs. 06-02, 08-02, and 10-02] continue to exceed the TAC adopted by the Commission and the scientific recommendations. Such potential catches could compromise the rebuilt state of this stock.

## ATLANTIC SWORDFISH SUMMARY

|  | North Atlantic | South Atlantic |
| :--- | :--- | :--- |
| Maximum Sustainable Yield ${ }^{1}$ | $13,730 \mathrm{t}(13,020-14,182)^{3}$ | $\sim 15,000 \mathrm{t}$ |
| Current (2010) TAC | $13,700 \mathrm{t}$ | $15,000 \mathrm{t}$ |

SWO-ATL-Figure 10. Posterior probability density estimates of MSY for South Atlantic swordfish from the catch-only model fitted to catch data from 1950 to 2009. Runs 1 and 2 refer to two scenarios with different assumptions for the intrinsic rate of population increase.

SWO-ATL-Figure 11. Summary figure of the current southern Atlantic swordfish stock status which includes the level of uncertainty on the knowledge of the state of the stock. Conditioned only on the catches, the model estimated a probability of 0.78 that the stock is not overfished and it is not undergoing overfishing.

SWO-ATL-Figure 12. Projections of median relative North Atlantic swordfish stock biomass and F from the base ASPIC model under different constant catch scenarios (10\15 thousand tons) North Atlantic swordfish stock.

SWO-ATL-Figure 13. North Atlantic swordfish, probability contours of $\mathrm{B}>\mathrm{B}_{\text {MSY }}$ and $\mathrm{F}<\mathrm{F}_{\text {MSY }}$ for the constant catch scenarios indicated over time. Red areas represent probabilities less than $50 \%$, yellow from $50-75 \%$, and green above $75 \%$. The $90^{\text {th }}, 75^{\text {th }}, 60^{\text {th }}$, and $50^{\text {th }}$ probability contours are also depicted.

SWO-ATL-Figure 14. South Atlantic, projected biomass levels under various catch scenarios. The bottom panel provides the details of the projections over a reduced time interval.

SWO-ATL-Figure 15. South Atlantic swordfish, probability contours of $\mathrm{B}>\mathrm{B}_{\text {MSY }}$ and $\mathrm{F}<\mathrm{F}_{\text {MSY }}$ (from the catch only model, both runs combined) for the constant catch scenarios indicated over time. Yellow areas represent probabilities from $50-75 \%$, and green above $75 \%$. The 90th, 75th, probability contours are also depicted. No probabilities were below $50 \%$.

### 8.9 SWO-MED-MEDITERRANEAN SWORDFISH

In the last 15 years Mediterranean swordfish production has fluctuated without any specific trend at levels higher than those observed for bigger areas such as the North and South Atlantic. The most recent assessment was conducted in 2010 (Anon. 2011f), making use of catch and effort information through 2008. The present report summarizes assessment results and readers interested in more detailed information on the state of the stock should consult the report of the latest stock assessment session.

## SWO-MED-1. Biology

Research results based on genetic studies have demonstrated that Mediterranean swordfish compose a unique stock separated from the Atlantic ones, although there is incomplete information on stock mixing and boundaries. However, mixing between stocks is believed to be low and generally limited to the region around the Straits of Gibraltar.

According to previous knowledge, the Mediterranean swordfish have different biological characteristics compared to the Atlantic stock, The growth parameters are different, and the sexual maturity is reached at younger ages than in the Atlantic, although more recent information for the Atlantic indicates that these differences may smaller than was previously thought. In the Mediterranean, mature females as small as 110 cm LJFL have been observed and the estimated size at which $50 \%$ of the female population is mature occurs at about 140 cm . According to the growth curves used by SCRS in the past for Mediterranean swordfish, these two sizes correspond to 2 and 3.5 year-old fish, respectively. Males reach sexual maturity at smaller sizes and mature specimens have been found at about 90 cm LJFL. Based on the fish growth pattern and the assumed natural mortality rate of 0.2 , the maximum yield would be obtained through instantaneous fishing at age 6 , while current catches are dominated, in terms of number, by fish less than 4 years old.

## SWO-MED-2. Fishery indicators

Annual catch levels fluctuate between 12,000-16,000 t . in the last 15 years without any specific trend. Those levels are relatively high and similar to those of bigger areas such as the North Atlantic. This could be related to higher recruitment levels in the Mediterranean than in the North Atlantic, different reproduction strategies (larger spawning areas in relation to the area of distribution of the stock) and the lower abundance of large pelagic predators (e.g. sharks) in the Mediterranean. Updated information on Mediterranean swordfish catch by gear type is provided in SWO-MED-Table 1 and SWO-MED-Figure 1. The total 2010 catch was $13,430 \mathrm{t}$, which is close to the mean of the 2006-2009 period. Gillnet catches show a declining trend in the last years due to the enforcement of a Mediterranean-wide driftnet ban. A complete closure of the Moroccan driftnet fishery is expected by the end of 2011. The biggest producers of swordfish in the Mediterranean Sea in the recent years are EU-Italy, Morocco, EU-Spain and EU-Greece. Also, Algeria, EU-Cyprus, EU-Malta, EU-Portugal, Tunisia and Turkey have fisheries targeting swordfish in the Mediterranean. Minor catches of swordfish have also been reported by Albania, Croatia, EU-France, Japan, and Libya. The Committee recognized that there may be additional fleets taking swordfish in the Mediterranean, for example, Egypt, Israel, Lebanon, Monaco and Syria, but the data are not reported to ICCAT or FAO.

Mediterranean swordfish landings showed an upward trend from 1965-1972, stabilized between 1973-1977, and then resumed an upward trend reaching a peak in 1988 ( $20,365 \mathrm{t}$; SWO-MED-Table 1, SWO-MED-Figure 1). The sharp increase between 1983 and 1988 may be partially attributed to improvement in the national systems for collecting catch statistics. Since 1988, the reported landings of swordfish in the Mediterranean Sea have declined fluctuating mostly between 12,000 to $16,000 \mathrm{t}$.

The main fishing gears used are surface longline and gillnets. Minor catches are also reported from harpoon, trap and recreational fisheries. Surface longlines are used all over the Mediterranean, while gillnets are still used in some areas and there are also countries known to be fishing with gillnets but not reporting their catches. However, following ICCAT recommendations for a general ban of driftnets in the Mediterranean, the gillnet fleet has been decreasing, although the total number of vessels cannot be determined from ICCAT statistics.

Preliminary results of experimental fishing surveys presented during the 2006 SCRS meeting indicated that selectivity of the surface longline targeting swordfish was more affected by the type and size of the bait, the depth of the set and the distance between branch lines rather than the type (circular vs. J-shaped) and the size of the hook. In general, American-style longlines capture less juvenile fish than the traditional Mediterranean longline gear, while a significant reduction of swordfish catches was found when using circle hooks.

A study based on fisheries data from the eastern Mediterranean presented during the 2009 SCRS suggested that there are no major differences in the age selection pattern among American and traditional longlines and confirmed previous findings regarding the higher catch efficiency of the American gear. It has been noted, however, that further studies in other Mediterranean areas are needed to verify that the estimated selection curves are independent of the stock distribution pattern.

Standardised CPUE series from the main longline and gillnet fisheries targeting swordfish, which were presented during the 2010 stock assessment session (Spanish longliners, Italian longliners, Greek longliners and Moroccan gillnetters), did not reveal any trend over time (SWO-MED-Figure 2). CPUE series, however, covered only the last 10-20 years and not the full time period of reported landings. Similarly to CPUE, not any trend over the past 20 years was identified regarding the mean fish weight in the catches (SWO-MED-Figure $3)$.

## SWO-MED-3. State of the stocks

Two forms of assessment (production modelling and age-structured analysis - XSA), indicated that current SSB levels are much lower than those in the early 80 's, although not any trend appears in the last 15 years. The extent of the decline differ among models, with the production model suggesting a decline of about $30 \%$, while XSA results indicate that current SSB level is about $1 / 4$ of that in the middle 80 's (SWO-MED-Figure 4). Results indicate that the fishery underwent a rapid expansion in the late 1980s resulting in Fs and catches above those that could support MSY. Estimates of population status from production modeling indicated that current stock level is slightly lower ( $\sim 5 \%$ ) to the optimum needed to achieve the ICCAT Convention objective, but these estimates have a high degree of uncertainty (CV~30\%). Additionally, it should be noted that production model biomass estimates are very sensitive to the assumption made about the initial stock biomass ratio. In general, the low contrast in the available catch-effort series affects the reliability of biomass estimates, as well as, the predictions of effort changes on future catch levels.

Results of yield-per-recruit analyses based on the analytical age-structured assessment in which we have more confidence indicated that the stock is in overfished condition and slight overfishing is taking place. Current (2008) SSB is $46 \%$ lower than the value that would maximize yield per-recruit. Current F is slightly higher to the estimated $\mathrm{F}_{\text {MSY }}$ (SWO-MED-Figure 5). Note, however, that these conclusions are based on deterministic analyses of the available data. The level of uncertainty in these estimates has not been evaluated.

The Committee again noted the large catches of small size swordfish, i.e., less than 3 years old (many of which have probably never spawned) and the relatively low number of large individuals in the catches. Fish less than three years old usually represent $50-70 \%$ of the total yearly catches in terms of numbers and $20-35 \%$ in terms of weight (SWO-MED-Figure 6). A reduction of the volume of juvenile catches would improve yield per recruit and spawning biomass per recruit levels.

## SWO-MED-4. Outlook

The assessment of Mediterranean swordfish indicates that the stock is below the level which can support MSY and that current fishing mortality slightly exceeds $\mathrm{F}_{\mathrm{MSY}}$. Overall results suggest that fishing mortality (and nearterm catches) needs to be reduced to move the stock toward the Convention objective of biomass levels which could support MSY and away from levels which could allow a rapid stock decline. A reduction of current F to the $F_{0.1}$ level would result to a substantial (about 40\%) long-term increase in SSB (SWO-MED-Figure 7).

Seasonal closure projections based on highly-aggregated data derived from the age-structured assessment and which assume no compensation in effort, no interaction with other management actions in place, and an improvement in recruitment with increasing spawning stock biomass (SSB), are forecast to be beneficial in moving the stock condition closer to the Convention objective, resulting in increased catch levels in the medium term, and reductions in the volume of juvenile catches. Although simulations suggest that the stock can be rebuild to the mid-1980s SSB levels only in the case of six month closures, SSB increases up to the optimum levels suggested by the yield-per-recruit analysis can be achieved within 2-3 generations (8-12 years) even under the current management status (2-month closure), provided that fishing mortality is kept on 2008 levels, which were quite lower than the previous years. Risk analysis, however, indicates that a small probability ( $<5 \%$ ) of stock collapse still exists in this case. Benefits from seasonal closures would be diminished if closure is applied in months of low fishing activity (December-January). It should be noted that seasonal closures, especially the longer ones, would result in significant catch reductions within the first few years after their application. Capacity reductions of $20 \%$ assuming no compensation in effort, or quotas equal to the $80 \%$ of the mean yield of
the last decade assuming no change in the selection pattern, could also result to stock rebuilt to optimum SSB levels. Results of the seasonal closure projections are summarized in SWO-MED-Figure 8.

## SWO-MED-5. Effects of current regulations

ICCAT imposed a Mediterranean-wide one month fishery closure for all gears targeting swordfish in 2008, followed by a two-month closure since 2009. Several countries have imposed technical measures, such as closed areas and seasons, minimum landing size regulations and license control systems. The EC introduced a driftnet ban in 2002 and in 2003 ICCAT adopted a recommendation for a general ban of this gear in the Mediterranean [Rec. 03-04]. Rec. 04-12 forbids the use of various types of nets and longlines for sport and recreational fishing for tuna and tuna-like species in the Mediterranean.

In past meetings, the Committee has reviewed the various measures taken by member countries and noted the difficulties in implementing some of the management measures, particularly that of minimum landing size.

## SWO-MED-6. Management recommendations

The Commission should adopt a Mediterranean swordfish fishery management plan which ensures that the stock will be rebuilt and kept in levels that are consistent with the ICCAT Convention objective. Given the uncertainties on optimum SSB level estimates and the rapid fishery expansion in the 1980s, which resulted in severe stock biomass declines, the SSB levels in the late 1980s may be also considered as a good $\mathrm{B}_{\text {MSY }}$ proxy for the stock. These levels, are around to $60,000-70,000 \mathrm{t}$, not very far however, from the currently estimated $\mathrm{B}_{\text {MSY }}$ value ( $\sim 62,000 \mathrm{t}$ ). Analysis has suggested that the seasonal closures have beneficial effects and can move the stock condition to the level which will support MSY, but the effect of the recently employed two-month closure could not be evaluated during the 2010 assessment session due to incomplete 2009 data.

Given that the current capacity in the Mediterranean swordfish fishery exceeds that needed to efficiently extract MSY, management measures aimed at reducing this capacity should also be considered part of a Mediterranean swordfish management plan adopted by the Commission.

## MEDITERRANEAN SWORDFISH SUMMARY

| Maximum Sustainable Yield | $\sim 14,600^{1}$ |
| :--- | :--- |
| Current (2010) Yield | $13,430 \mathrm{t}$ |
| Current (2008) Replacement Yield | $\sim 12,100 \mathrm{t}^{1}$ |

SWO-MED-Figure 1. Cumulative estimates of swordfish catches ( t ) in the Mediterranean by major gear types, for the period 1950-2010 (the 2010 data are provisional).

SWO-MED-Figure 2. Time series of standardized CPUE rates scaled to the corresponding mean value for the Spanish longliners (SP_LL), Italian longliners (IT_LL), Greek longliners (GR_LL), and Moroccan gillnetters (MO_GN).

SWO-MED-Figure 3. Time series of mean fish weight in the catches.

SWO-MED-Figure 4. Total and spawning stock biomass (SSB) estimates (grey color) obtained from the agestructured analysis.

SWO-MED-Figure 5. Time trends for stock status ( $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ ) derived from the age-structured analysis. The open circle indicates the ratio estimates for the last assessment year (2008).

SWO-MED-Figure 6. Proportion of catch numbers (left) and catch weight (right) at age by year.

SWO-MED-Figure 7. Equilibrium curves estimated from the yield per recruit analysis.

SWO-MED-Figure 8. Scenario estimates assuming a Beverton-Holt stock/recruitment model. From left to right and top to bottom: current management, 4-month closure, 6month closure, $20 \%$ capacity reduction, quota equal to $80 \%$ of the mean catch of the last decade, quota equal to the mean catch of the last decade.

### 8.10 SBF - SOUTHERN BLUEFIN TUNA

The Commission for the Conservation of Southern Bluefin Tuna (CCSBT) is charged with assessing the status of southern bluefin tuna. The reports are available from CCSBT.

### 8.11 SMT - SMALL TUNAS

## SMT-1. Generalities

Small tunas include the following species:

- BLF Blackfin tuna (Thunnus atlanticus)
- BLT Bullet tuna (Auxis rochei)
- BON Atlantic bonito (Sarda sarda)
- BOP Plain bonito (Orcynopsis unicolor)
- BRS Serra Spanish mackerel (Scomberomorus brasiliensis)
- CER Cero (Scomberomorus regalis)
- FRI Frigate tuna (Auxis thazard)
- KGM King mackerel (Scomberomorus cavalla)
- KGX Scomberomorus unclassified (Scomberomorus spp.)
- LTA Little tunny (Euthynnus alletteratus)
- MAW West African Spanish mackerel (Scomberomorus tritor)
- SSM Atlantic Spanish mackerel (Scomberomorus maculatus)
- WAH Wahoo (Acanthocybium solandri)
- DOL Dolphinfish (Coryphaena hippurus)

Knowledge on the biology and fishery of small tunas is very fragmented in several areas. Furthermore, the quality of the knowledge is very different according to the species concerned. This is due in large part because many of these species are often perceived to have little economic importance compared to other tuna and tunalike species, and owing to the difficulties in conducting sampling of the landings from artisanal fisheries, which constitute a high proportion of the fisheries exploiting small tuna resources. The large industrial fleets often discard small tuna catches at sea or sell them on local markets mixed with other by-catches, especially in Africa (SCRS/2009/147). The amount caught is rarely reported in logbooks; however observer programs from purse seine fleets have recently provided estimates of catches of small tunas (Amandé et al. 2010).

Small tuna species have a very high relevance from a socio-economic point of view, because they are important for many coastal communities in all areas and are a main source of food. The socio-economic value is often not evident because of the underestimation of the total figures, due to the above mentioned difficulties in data collection. Several statistical problems are also caused by misidentification. The small tuna species can reach high levels of catches and values in some years.

Scientific collaboration among ICCAT, RFOs and countries in the various regions is imperative to advance understanding of the distribution, biology and fishery of these species.

## SMT-2. Biology

These species are widely distributed in the tropical and subtropical waters of the Atlantic Ocean and several are also distributed in the Mediterranean Sea and the Black Sea. Some species extend their range even to colder waters, like the North and South Atlantic Ocean. They often form large schools with other small sized tunas or related species in coastal and high seas waters.

Generally, the small tuna species have a varied diet with a preference for small pelagics (e.g., clupeids, mullets, carangids, etc.). These species feed also on crustaceans, mollusks and cephalopods. Many of these species are also prey of large tunas, marlins and sharks. The reproduction period varies according to species and areas and spawning generally takes place near the coast in oceanic areas, where the waters are warmer. The growth rate currently estimated for these species is very rapid for the first two or three years, and then slows as these species reach size-at-first maturity. Studies about the migration patterns of small tuna species are very rarely available, due to the practical difficulties in manipulating and tagging these species.

In general, there is a lack of information on biological parameters for these species, especially for West Africa and the Caribbean and South America. A new document regarding the length -weight relationship of dolphinfish (Coryphaena hippurus) as bycatch in the longline fisheries of the Western Mediterranean was presented to the species group meeting (SCRS/2011/183).

## SMT-3. Description of the fisheries

Small tunas are exploited mainly by coastal fisheries and artisanal fisheries, although substantial catches are also made as target species and as by-catch by purse seine, mid-water trawlers (i.e., pelagic fisheries of West AfricaMauritania), handline and small scale gillnets. Unknown quantities of small tuna also comprise the incidental catches of some longline fisheries. The increasing importance of FAD fisheries in the eastern Caribbean and in other areas has improved the efficiency of artisanal fisheries in catching small tunas. Various species are also caught by the sport and recreational fisheries. A new document describing the Venezuelan industrial surface fleets and small scale fisheries catching the blackfin tuna was presented to this species group (SCRS/2011/122).

Despite of the scarce monitoring of various fishing activities in some areas, all the small tuna fisheries have a high socio-economic relevance for most of the coastal countries concerned and for many local communities, particularly in the Mediterranean Sea, in the Caribbean region and in West Africa.

SMT-Table 1 shows historical landings of small tunas for the 1986 to 2010 period although the data for the last years are preliminary. This table does not include species reported as "mixed" or "unidentified", as was the case in the previous years, since these categories include large tuna species. There are more than 10 species of small tunas, but only five of these account for about $88 \%$ of the total reported catch by weight. These five species are: Atlantic bonito (Sarda sarda), frigate tuna (Auxis thazard) which may include some catches of bullet tuna (Auxis rochei), little tunny (Euthynnus alletteratus), king mackerel (Scomberomorus cavalla), and Atlantic Spanish mackerel (Scomberomorus maculatus) (SMT-Figure 2). In 1980, there was a marked increase in reported landings compared to previous years, reaching a peak of about 147,202 t in 1988 (SMT-Figure 1). Reported landings for the 1989-1995 period decreased to approximately $91,907 \mathrm{t}$, and then an oscillation in the values in the following years, with a minimum of $59,148 \mathrm{t}$ in 2008 and a maximum of $129,353 \mathrm{t}$ in 2005 . Overall trends in the small tuna catch may mask declining trends for individual species because annual landings are often dominated by the landings of a single species. These fluctuations seem to be related to unreported catches, as these species generally comprise part of the by-catch and are often discarded, and therefore do not reflect the real catch.

A preliminary estimate of the total nominal landings of small tunas in 2010 is $72,195 \mathrm{t}$. The Small Tunas Species Group pointed out the relative importance of small tuna fisheries in the Mediterranean and the Black Sea, which account for about $28 \%$ of the total reported catch in the ICCAT area for the period 1980-2010.

Despite the recent improvements in the statistical information provided to ICCAT by several countries, the Committee also noted that uncertainties remain regarding the accuracy and completeness of reported landings in all areas. There is a general lack of information on the mortality of these species as by-catch, exacerbated by the confusion regarding species identification.

## SMT-4. State of the stocks

There is little information available to determine the stock structure of many small tuna species. The Committee suggests that countries be requested to submit all available data to ICCAT as soon as possible, in order to be used in future meetings of the Committee.

Generally, current information does not allow the Committee to carry out an assessment of stock status of the majority of the species. Some analyses will be possible in future if data availability improves with the same trend of the latest years. Nevertheless, few regional assessments have been carried out. Assessments of stocks of small tunas are also important because of their position in the trophic chain where they are the prey of large tunas, marlins and sharks and they are predators of small pelagic. It may therefore be best to approach assessments of small tunas from the ecosystem perspective.

## SMT-5. Outlook

Although there are some improvement in the availability of catch and biological data for small tuna species particularly in the Mediterranean and the Black Sea, biological information, catch and effort statistics for these species remain incomplete for many of the coastal and industrial fishing countries. Given that, many of these species are of a high socio-economic importance to coastal communities, therefore the Committee recommends that further studies be conducted on small tuna species due to the small amount of information available.

## SMT-6. Effects of current regulations

There are no ICCAT regulations in effect for small tunas. Several regional and national regulations are in place.

## SMT-7. Management recommendations

No management recommendations have been made.

### 8.12 SHK - SHARKS

The status of the stocks of blue shark (Prionace glauca) and shortfin mako (Isurus oxyrinchus), resulting from the 2008 ICCAT assessment (Anon. 2009b), and the stock of porbeagle (Lamna nasus), which was assessed jointly with ICES in 2009, are given in the 2010 SCRS Report. The information from the Ecological Risk Assessment (ERA) for nine species of pelagic elasmobranches carried out in 2008 (Cortés et al. 2010) is also included in the 2010 SCRS Report.

In 2011, a data preparatory meeting was held in response to the Recommendation by ICCAT on Atlantic Shortfin Mako Sharks Caught in Association with ICCAT Fisheries [Rec. 10-06] and to define the steps to follow in carrying out the ERA envisaged for 2012. The full report of the data preparatory meeting is included in SCRS/2011/017.

## SHK-1. Biology

A great variety of shark species are found within the ICCAT Convention area, from coastal to oceanic species. Biological strategies of these sharks are very diverse and are adapted to the needs within their respective ecosystems where they occupy a very high position in the trophic chain as active predators. Therefore, generalization as regards to the biology of these very diverse species results in inevitable inaccuracies, as would occur for teleosts. To date, ICCAT has prioritized the biological study and assessment of the major sharks of the epipelagic system as these species are more susceptible of being caught as by-catch by oceanic fleets targeting tuna and tuna-like species. Among these shark species there are some of special prevalence and with an extensive geographical distribution within the oceanic-epipelagic ecosystem, such as the blue shark and shortfin mako shark, and others with less or even limited prevalence, such as porbeagle, hammerhead sharks, thresher sharks, white sharks, etc.

Blue shark and shortfin mako sharks show a wide geographic distribution, most often between $50^{\circ} \mathrm{N}$ and $50^{\circ} \mathrm{S}$ latitude. On the contrary, porbeagle show a distribution that is restricted to cold-temperate waters, preferably close to the continental shelf of both hemispheres where this species rarely overlaps with the fishing activity directed at tunas and tuna-like species. These three species have an ovoviviparous reproductive strategy, which increases the probability of survival of their young, with litters from only a few individuals in the case of shortfin mako and porbeagle, to abundant litters of about 40 pups in the case of blue shark. Their growth rates differ between sexes and among these three species. Females often reach first maturity at a large size. A characteristic of these species is usually their tendency to segregate temporally and spatially by size-sex, according to their respective processes of feeding, mating-reproduction, gestation and birth. Numerous aspects of the biology of these species are still poorly understood or completely unknown, particularly for some regions, which contributes to increased uncertainty in quantitative and qualitative assessments.

## SHK-2. Fishery indicators

Earlier reviews of the shark database resulted in recommendations to improve data reporting on shark catches. Though global statistics on shark catches included in the database have improved, they are still insufficient to permit the Committee to provide quantitative advice on stock status with sufficient precision to guide fishery management toward optimal harvest levels. Reported and estimated catches for blue shark, shortfin mako and porbeagle are provided in SHK-Table 1 and Figures 1 to 4.

A number of standardized CPUE data series for blue shark and shortfin mako were presented in 2008 as relative indices of abundance. The Committee placed emphasis on using the series that pertained to fisheries that operate in oceanic waters over wide areas. SHK-Figure 5 presents the central tendency of the available series for the four stocks of these species.

Considering the quantitative and qualitative limitations of the information available to the Committee, the results presented in 2008, as those of the 2004 assessment (Anon. 2005), are not conclusive. During the porbeagle assessment in 2009 (Anon. 2010a), standardized CPUE data were presented for three of the four stocks (NE, NW and SW; SHK-Figure 6). These series when referring to fisheries targeting porbeagle could fail to reflect the global abundance of the stock and where they refer to sharks caught as by-catch they could be highly variable. In 2010, only new information from Japan on the CPUE of shortfin mako and Porbeagle was presented. However, it was suggested that the recently developed method used for the stratification of the areas for the analysis of CPUE should be sent to the ICCAT Secretariat.

With regard to the species for which ERAs were conducted, the Committee understands that, in spite of existing uncertainties, results make it possible to identify those species that are more vulnerable to prioritize research and management measures (SHK-Table 2). These ERAs are conditional on the biological variables used to estimate productivity as well as the susceptibility values for the different fleets.

## SHK-3. State of the Stocks

Ecological risk assessments for 11 priority species of sharks (including blue shark and shortfin mako) caught in ICCAT fisheries demonstrated that most Atlantic pelagic sharks have exceptionally limited biological productivity and, as such, can be overfished even at very low levels of fishing mortality. Specifically, the analyses indicated that bigeye threshers, longfin makos, and shortfin makos have the highest vulnerability (and lowest biological productivity) of the shark species examined (with bigeye thresher being substantially less productive than the other species). All species considered in the ERA, particularly smooth hammerhead, longfin mako, bigeye thresher and crocodile sharks, are in need of improved biological data to evaluate their biological productivity more accurately and thus specific research projects should be supported to that end. SHK-Table 2 provides a productivity ranking of the species considered. ERAs should be updated with improved information on the productivity and susceptibility of these species.

## SHK-3.1 Blue shark

For both North and South Atlantic blue shark stocks, although the results are highly uncertain, biomass is believed to be above the biomass that would support MSY and current harvest levels below F $\mathrm{F}_{\text {MSY }}$. Results from all models used in the 2008 assessment (Anon. 2009c) were conditional on the assumptions made (e.g., estimates of historical catches and effort, the relationship between catch rates and abundance, the initial state of the stock in the 1950s, and various life-history parameters), and a full evaluation of the sensitivity of results to these assumptions was not possible during the assessment. Nonetheless, as for the 2004 stock assessment (Anon. 2005c), the weight of available evidence does not support hypotheses that fishing has yet resulted in depletion to levels below the Convention objective (SHK-Figure 7).

## SHK-3.2 Shortfin mako shark

Estimates of stock status for the North Atlantic shortfin mako obtained with the different modeling approaches applied in 2008 were much more variable than for blue shark. For the North Atlantic, most model outcomes indicated stock depletion to about $50 \%$ of biomass estimated for the 1950 s. Some model outcomes indicated that the stock biomass was near or below the biomass that would support MSY with current harvest levels above $\mathrm{F}_{\mathrm{MSY}}$, whereas others estimated considerably lower levels of depletion and no overfishing (SHK-Figure 7). In light of the biological information that indicates the point at which $\mathrm{B}_{\mathrm{MSY}}$ is reached with respect to the carrying capacity which occurs at levels higher than for blue sharks and many teleost stocks. There is a non-negligible probability that the North Atlantic shortfin mako stock could be below the biomass that could support MSY. A similar conclusion was reached by the Committee in 2004, and recent biological data show decreased productivity for this species. Only one modeling approach could be applied to the South Atlantic shortfin mako stock, which resulted in an estimate of unfished biomass which was biologically implausible, and thus the Committee can draw no conclusions about the status of the South stock.

## SHK-3.3 Porbeagle shark

In 2009, the Committee attempted an assessment of the four porbeagle stocks in the Atlantic Ocean: Northwest, Northeast, Southwest and Southeast (Anon. 2010e). In general, data for southern hemisphere porbeagle are too limited to provide a robust indication on the status of the stocks. For the Southwest, limited data indicate a decline in CPUE in the Uruguayan fleet, with models suggesting a potential decline in porbeagle abundance to levels below MSY and fishing mortality rates above those producing MSY (SHK-Figure 8). But catch and other data are generally too limited to allow definition of sustainable harvest levels. Catch reconstruction indicates that reported landings grossly underestimate actual landings. For the Southeast, information and data are too limited to assess their status. Available catch rate patterns suggest stability since the early 1990s, but this trend cannot be viewed in a longer term context and thus are not informative on current levels relative to $\mathrm{B}_{\text {MSY }}$.

The northeast Atlantic stock has the longest history of commercial exploitation. A lack of CPUE data for the peak of the fishery adds considerable uncertainty in identifying the current status relative to virgin biomass. Exploratory assessments indicate that current biomass is below $\mathrm{B}_{\mathrm{MSY}}$ and that recent fishing mortality is near or above $\mathrm{F}_{\text {MSY }}$ (SHK-Figure 9). Recovery of this stock to $\mathrm{B}_{\text {MSY }}$ under no fishing mortality is estimated to take ca.

15-34 years. The current EU TAC of 436 t in effect for the northeast Atlantic may allow the stock to remain stable, at its current depleted biomass level, under most credible model scenarios. Catches close to the current TAC (e.g. 400 t ) could allow rebuilding to $\mathrm{B}_{\text {MSY }}$ under some model scenarios, but with a high degree of uncertainty and on a time scale of $60(40-124)$ years.

An update of the Canadian assessment of the northwest Atlantic porbeagle stock indicated that biomass is depleted to well below $\mathrm{B}_{\mathrm{MSY}}$, but recent fishing mortality is below $\mathrm{F}_{\text {MSY }}$ and recent biomass appears to be increasing. Additional modelling using a surplus production approach indicated a similar view of stock status, i.e., depletion to levels below $\mathrm{B}_{\text {MSY }}$ and current fishing mortality rates also below $\mathrm{F}_{\text {MSY }}$ (SHK-Figure 10). The Canadian assessment projected that with no fishing mortality, the stock could rebuild to $\mathrm{B}_{\text {MSY }}$ level in approximately 20-60 years, whereas surplus-production based projections indicated 20 years would suffice. Under the Canadian strategy of a $4 \%$ exploitation rate, the stock is expected to recover in 30 to 100+ years according to the Canadian projections.

## SHK-4. Management Recommendations

Precautionary management measures should be considered for stocks where there is the greatest biological vulnerability and conservation concern, and for which there are very few data. Management measures should ideally be species-specific whenever possible.

For species of high concern (in terms of overfishing), and for which a high survivorship is expected in fishing gears after release, the Committee recommends that the Commission prohibit retention and landing of the species to minimize fishing mortality. The Committee recognizes that the difficulty in identifying look-alike species may complicate compliance with management measures adopted for those species

For all the species, but particularly for those which can be easily misidentified, it is essential that the Committee advances data collection and research on life history, together with the interactions with tuna fisheries, with the final objective of assessing the status of the stocks. Until such information is made available, the Commission should consider taking effective measures to reduce the fishing mortality of these stocks. These measures may include minimum or maximum size limits for landing (for protection of juveniles or the breeding stock, respectively); and any other technical mitigation measures such as gear modifications, time-area restrictions, or others, as appropriate. Such management actions should be combined with research activities, in order to provide information on their effectiveness.

The SCRS welcomed the conservation and management measures adopted by the Commission in the past two years regarding the species ranked as the most vulnerable in the last Ecological Risk Assessment and for which almost no data have been submitted (bigeye thresher, oceanic whitetip shark and hammerhead shark). At the same time, the SCRS expressed concern with the fact that no conservation and management measures have been adopted so far for the top ranked species in the ERA, the silky shark, Carcharhinus falciformis. Accordingly, the SCRS recommended that proper conservation and management measures, similar to those adopted for those species, be also adopted for the silky shark.

Both porbeagle stocks in the northwest and northeast Atlantic were estimated to be overfished, with the northeastern stock being more highly depleted. The main source of fishing mortality on these stocks is from directed porbeagle fisheries which are not under the Commission’s direct mandate. Those fisheries are managed mostly by ICCAT Contracting Parties through national legislation which includes quotas and other management measures.

The Committee also recommends that countries initiate research projects to investigate means to minimize bycatch and discard mortality of sharks, with a particular view to recommending to the Commission complementary measures to minimize porbeagle by-catch in fisheries for tuna and tuna-like species. For porbeagle sharks, the Committee recommends that the Commission work with countries catching porbeagle, particularly those with targeted fisheries, and relevant RFMOs to ensure recovery of North Atlantic porbeagle stocks and prevent overexploitation of South Atlantic stocks. In particular, porbeagle fishing mortality should be kept to levels in line with scientific advice and with catches not exceeding current level. New targeted porbeagle fisheries should be prevented, porbeagles retrieved alive should be released alive, and all catches should be reported. Management measures and data collection should be harmonized as much as possible among all relevant RFMOs dealing with these stocks, ICCAT should facilitate appropriate communication.

The Committee recommends that joint work with the ICES Working Group on Elasmobranch Fishes should be continued. In addition, stocks of mutual interest and areas of overlap, particularly species occurring in the Mediterranean Sea, should be discussed.

The Committee recommends that scientific observers be allowed to collect biological samples (vertebrae, tissues, reproductive tracts, stomachs) from species whose retention is prohibited by current regulations.

The Committee recommends that the CPCs explore methods to estimate catches of sharks in purse seine and artisanal fisheries.

## NORTH ATLANTIC BLUE SHARK SUMMARY

## 2007 Yield

Provisional Yield (2010)
Relative Biomass:

Relative Fishing Mortality:

|  | ${ }^{61,845 \mathrm{t}^{1}}$ |
| :--- | :--- |
|  | $37,238 \mathrm{t}^{2}$ |
| $\mathrm{~B}_{2007} / \mathrm{B}_{\text {MSY }}$ | $1.87-2.74^{3}$ |
| $\mathrm{~B}_{2007} / \mathrm{B}_{0}$ | $0.67-0.93^{4}$ |

SHK-Table 2. Productivity values ranked from lowest to highest.

| Species | Productivity $(r)$ | Productivity rank |
| :--- | :---: | :---: |
| BTH (Alopias superciliosus) | 0.010 | 1 |
| SMA (Isurus oxyrinchus) | 0.014 | 2 |
| LMA (Isurus paucus) | 0.014 | 3 |
| POR (Lamna nasus) | 0.053 | 4 |
| FAL (Carcharhinus falciformis) | 0.076 | 6 |
| OCS (Carcharhinus longimanus) | 0.087 | 7 |
| SPL (Sphyrna lewini) | 0.090 | 8 |
| SPZ (Sphyrna zygaena) | 0.124 | 9 |
| ALV (Alopias vulpinus) | 0.141 | 10 |
| PST (Pteroplatytrygon violacea) | 0.169 | 11 |
| BSH (Prionace glauca) | 0.301 | 12 |
| CRO (Pseudocarcharias kamoharai) | - | - |

SHK-Figure 1. Blue shark (BSH) and shortfin mako (SMA) catches reported to ICCAT (Task-I) and estimated by the Committee.

SHK-Figure 2. Potential catch of porbeagle by non-reporting longline fleets using catch ratios for the NW stock. Limited observations across the time-series result in an unquantified uncertainty in the estimates.

SHK Figure 3. Left plate: Estimated catch of porbeagle by non-reporting longline fleets using catch ratios for the SW stock. Very limited observations across the time-series result in a high but unquantified uncertainty in the estimates. Right plate: Comparison of estimates for non-reporting longline fleets with reported catch levels held in the Task I data set for the SW stock area.

SHK Figure 4. Catch by flag of porbeagle sharks from the northeastern Atlantic used in the assessment. While these catches are considered the best available,, they are believed to underestimate the pelagic longline catches for this species.

SHK-Figure 5. Average trends in the CPUE series used in the assessments of blue shark (BSH) and shortfin mako (SMA). The averages were calculated by weighting the available series either by their relative catch or by the relative spatial coverage of the respective fisheries.

SHK-Figure 6. CPUE series for the porbeagle NW stock (upper figures), NE stock (lower left figures) and SW stock (lower right figure).

SHK-Figure 7. Phase plots summarizing base scenario outputs for the current stock status of blue shark (BSH) and shortfin mako (SMA). BSP=Bayesian surplus production model; CFASPM=catch-free, age-structured production model. The shaded box represents the area at which the biomass at MSY is estimated to be reached. Any points inside or to the left of the box indicate the stock is overfished (with respect to biomass). Any points above the horizontal line indicate overfishing (with respect to F ) is occurring.

SHK-Figure 8. Phase plot for the southwest Atlantic porbeagle, showing status in 2009 from both the BSP model runs (diamonds) and the catch free age structured production model (square) results. Error bars are plus and minus one standard deviation.

SHK-Figure 9. Phase plot showing current status of northeast Atlantic porbeagle for the BSP model (diamonds) and the ASPM model (squares). Error bars are plus and minus one standard deviation.

SHK-Figure 10. Phase plot showing the northwest Atlantic porbeagle expected value of $\mathrm{B} / \mathrm{B}_{\mathrm{MSY}}$ and $\mathrm{F} / \mathrm{F}_{\mathrm{MSY}}$ in the current year, which is either 2005 (diamonds) or 2009 (circles), as well as approximate values from Campana et al. (2010) (squares). B/B $\mathrm{B}_{\text {MSY }}$ was approximated from Campana et al. (2010) as N2009/N1961 times 2. Error bars are plus and minus one standard deviation.

## 9. Report of inter-sessional meetings

The reports of the inter-sessional meetings held in 2011 were presented, with special emphasis not directly related to the stock assessments because their results are not included and presented in the Executive Summaries. The following meetings were presented.

### 9.1 Workshop on the use of R tools in the data preparatory work ICCAT-SCRS

The workshop was held in Madrid, February 7-11, with the objective of developing the skills needed within Species Groups; both during data preparatory meetings and stock assessments. Participants came from a range of CPCs, both developed and developing states (with help from the various ICCAT funds). The topics covered were working with data, accessing ICCAT databases and conducting exploratory data analyses. The types of tasks performed in stock assessment were also covered, i.e. conversion of catch-at-size to catch-at-age, standardisation of CPUE as well as conducting stock assessments and presentation of advice in the form of "Kobe Strategy Matrices".

### 9.2 Working Group on the Organization of the SCRS

The meeting on the organisation of the SCRS, Madrid, March 2-4, reviewed various issues related to the increased demands on the SCRS and implications for Secretariat support. Topics included the Secretariat's role in providing scientific support to the SCRS and participation of CPC scientists at meetings of the SCRS. It was also recognised that the work load of the SCRS had increased due to the need to address a wide variety of recommendations from the Commission. In particular, in relation to the implementation of the Precautionary Approach and the incorporation of advice on the Ecosystem Based Approach to Fisheries Management. Other issues considered were the importance of agreeing a data confidentiality policy to ensure scientific access to data, and the implications for the Secretariat and SCRS discussed.

Other topics covered were how to agree a standard format for scientific reports and collaboration with other tRFMOs.

Recommendations included the need for increased scientific analytical support if more use was to be made of statistical stock assessment methods and Management Strategy Evaluation. Currently: data analyses and research supporting stock assessments are the joint responsibility of CPC scientists and Secretariat professional staff. The increased demands on the SCRS and the need for additions to Secretariat staff, e.g. for data management and bycatch coordination, were discussed. The importance of capacity building and methods for quality assurance and transparency were also discussed.

Document SCRS/2011/012 contains the detailed report of the meeting.

### 9.3 2011 Blue Marlin Stock Assessment Session and White Marlin Data Preparatory Meeting

The meeting for the blue marlin stock assessment and white marlin data preparatory was held in Madrid in April 25 to 29, 2011. The meeting had the dual purpose of producing an assessment of blue marlin to estimate reference points and update management recommendations, and preparing the general basic fishery data, such as estimates of total harvest and relative abundance estimates, and the specific data to support the models to be used in the next white marlin assessment in 2012. The blue marlin assessment meeting achieved its main goals by producing new benchmarks for the stock and suggesting new management recommendations to rebuild the stock. During the white marlin data preparatory meeting, in addition to obtaining estimates of total removals and partial information on abundance indices, it was recognized that the next white marlin assessment be considered as a mixed species stock assessment because of the mixture with other similar species.

The detail report of the meeting is presented as document SCRS/2011/013.

## Discussion

The Committee acknowledges the analyses and presentation regarding the blue marlin assessment. It was noted that the implementation of complex models such as statistically integrated models (SS3) are sensitive to the assumptions of the parameters estimated. Considering the condition of blue marlin being a by-catch species in some important fisheries, the inherent uncertainty with regard to data and the productivity of the stock was recognized.

### 9.4 Inter-Sessional Meeting of the Sub-Committee on Ecosystems

The inter-sessional meeting of the Sub-Committee on Ecosystems was held in Miami, Florida, USA from May 9 to 13 , 2011. During this meeting, the Sub-Committee discussed the following:

1. Spatial production models for multi-species and multi-area stock assessments.
2. The integration of environmental variables in the standardization of CPUE (e.g. effect of expansion in oxygen minimum zones).
3. Ecosystem based indicators.
4. By-catch estimation procedures and measures of precision.
5. Seabird and sea turtle by-catch mitigation measures.
6. Safe release and handling protocols for sea turtles.

The Group also considered a summary of the International Circle Hook Symposium, made recommendations to ICCAT regarding the job description of the proposed by-catch coordinator, and recommended a reorganization of the Sub-Committee, specifically the addition of an Ecosystems Rapporteur.

The Detail Report of the meeting is presented as document SCRS/2011/014.

### 9.5 Tropical Tuna Species Group Intersessional Meeting on the Ghanaian Statistics Analysis (Phase II)

An inter-sessional meeting of the Tropical Tuna Species Group on the Ghanaian Statistics Analysis (Phase II) met in Madrid, on May 30 to June 3, 2011. The objective of the meeting had been defined in the 2011 Work Plan for Tropical Species approved by the SCRS (ICCAT, 2011). This included the revision of the data for the eastern tropical purse seine fisheries, in particular the Ghanaian statistics, as well as the accounting of faux poissons.

This year thorough review of data has been conducted in order to better understand aspects of the data collection, processing and reporting systems.

The work during the meeting focused on obtaining the best scientific estimates of catch, effort and size data for the three main species of tropical tunas. These estimates are important in order to allow the SCRS to better estimate the stock status and to provide more accurate responses to the Commission.

The Report of the meeting is presented as document SCRS/2011/016.

### 9.6 Sharks Data Preparatory Meeting to apply Ecological Risk Assessment

The Shark Species Group met on Madrid in June 20 to 24, 2011, to increase the current database in order to update in 2012 the Ecological Risk Assessment (ERA) carried out in 2008 (Cortés et al. 2010). On this occasion, the Group increased the number of species to 18 to apply the ERA.

The Report of the meeting is presented as document SCRS/2011/017.

## Discussion

Discussion focused on the use of the ERA as a first approach to the stock assessment of the resources and the importance of this approach against the traditional stock assessment methods.

The Committee considered that this type of analysis does not replace the traditional stock assessment methods, but that they were alternative and/or supplemental methods which were applied when the available data did not allow the use of conventional models. Likewise, it was considered that the report of the meeting (SCRS/2011/017) included detailed information on the scope of the ERA.

The Committee recognized that currently this approach was only applied to industrial longline and that it would be positive if, in the future, it could include more information on other fleets, in particular, the artisanal fleets. The Committee valued the information which these methods contributed in providing scientific advice to the Commission when the available data were insufficient.

### 9.7 Joint Meeting of the ICCAT Working Group on Stock Assessment Methods and the Bluefin Tuna Species Group to analyze assessment methods developed under the GBYP and electronic tagging

The meeting was held in Madrid, Spain, June 27-July 1, 2011 with the objective of reviewing of current development of stock assessment methods (GBYP), conducting Meta-analysis for investigation of key parameters such as steepness, virgin biomass or $K$, $r$ and $M$ and investigating limit, threshold and target reference points as part of HCRs to manage risk of exceeding key reference points.

The Detail Report of the meeting is presented as document SCRS/2011/018.

### 9.8 South Atlantic Albacore and Mediterranean Albacore Assessment Sessions

The meeting was held in Madrid, Spain, July 25-29, 2011. The Mediterranean stock was evaluated for the first time. An update of the 2007 assessment was carried out for the Southern stock. The Albacore executive report summarizes the main results for both stocks.

The Detailed Report of the meeting is presented as document SCRS/2011/019.

### 9.9 Yellowfin Stock Assessment Session

The SCRS conducted a comprehensive assessment of Atlantic yellowfin tuna on September 5-12, 2011, using the available data (catch, effort and size statistics).

The Detailed Report of the meeting is presented as document SCRS/2011/020.

## 10. Report of Special Research Programs

### 10.1 Atlantic-wide Bluefin Tuna Research Programme (GBYP)

Dr. Antonio Di Natale, Program Coordinator, presented the report on the Atlantic-wide Bluefin Tuna Research Programme (GBYP) activities carried out in 2011.

The Report was adopted and is attached as Appendix 5.

### 10.2 Enhanced Research Program for Billfish

The report of the Program for Enhanced Research on Billfish, together with the proposed budget for 2012, was presented by the Program Coordinator, Dr. David Die.

The report was adopted and is attached as Appendix 6.

## 11. Report of the Sub-Committee on Statistics

Dr. Gerald Scott presented the Report of the Sub-Committee on Statistics (Appendix 7) which held its session in Madrid, September 26 and 27, 2011. With regards to the official statistics submitted by CPC (Task I and II) the following was noted: (a) The importance and potential use of the Fleet Characteristic data, but given the variability of the information provided it was recommended to crosscheck it with other vessel lists submitted to the Secretariat for validation; (b) The decreasing trend of conventional and electronic tag reports, thus it was recommended that the Secretariat update the list of CPC Tagging Correspondents and remind them to submit this information to the Secretariat; (c) Under the recently adopted Data Confidentiality policy by the Commission, the SCRS may further utilize more detailed information for scientific purposes, such the VMS data. With respect to VMS data it recommends to increase the resolution of the information received by the VMS signal, and to extend the VMS requirements to all main tuna operations.

The Sub-Committee also noted the importance of the documentation of the ICCAT database, and reiterated it as a priority task for the Secretariat. As regards to data quality and the impact on stock evaluations, the SubCommittee recommended to update the evaluation of data availability and focus more on methods or protocols to
perform data quality evaluations rather than compliance submission controls. To this respect it was also proposed as future work for this Sub-Committee to seek expertise to explore evaluation of auxiliary data compiled by the Secretariat such as the market related reports.

In response to the Commission Rec. 10-10, this Sub-Committee reviewed and summarized the responses provided by CPCs regarding the CPC Observer programs in tuna fisheries. The low response by CPCs, and the different level of information provided was noted. It was recommended to send a simple form by the Secretariat to CPCs and update the information received in preparation for the response to be provided to the Commission in 2012.

Clarification of the quality and usefulness of the cannery data provided by ISSF to the Secretariat was requested regarding comments raised in earlier discussions. The Sub-Committee Chair reported that this data was fully utilized in the revision of the Ghanaian and other tuna fisheries statistics. Scientists that participated in this evaluation commented on the importance and high value of the information provided by ISSF cooperating canneries in support of the work of the Committee. It was noted that use of these data are in fact critical in identifying possible problems in species classification and enabled the Group to develop hypotheses that can be tested through controlled experiments to explain differences and thus advise on methods to overcome possible inconsistencies. The Committee agreed that the value of data provided by ISSF cooperating canneries was high and encouraged the continued reporting of these data to ICCAT.

Finally, the record high participation of scientists at SCRS Species Working Group meetings was noted to have led to a very crowded meeting room. The Secretariat noted that larger facilities (larger meeting rooms) or improvement(s) at the Secretariat location is limited by the regulations of the hosting administration.

## 12. Report of the Sub-Committee on Ecosystems

Dr. Shannon Cass-Calay, the Convener of the Sub-Committee on Ecosystems, presented the report of the intersessional meeting held in Miami (USA), May 9 to 13, 2011, and the recommendations and conclusions of the Joint Technical By-catch Working Group (JTBWG), which met at the Kobe III tuna RFMOs meeting. The JTBWG agreed to meet electronically every three months and to meet in person whenever possible in conjunction with Kobe meetings or, in the absence of a Kobe meeting, every three years. Over the next several years the Working Group proposes the following work plan:

- Harmonization of data collection
- Development of harmonized identification guides and release protocols
- Identify and recommend research priorities
- Prioritization of collaborative work
- Progress BMIS information sharing website
- Funding sources
- Compliance with data reporting requirements

The Committee approved the recommendations adopted by the Sub-Committee on Ecosystems which are included in the general recommendations of the SCRS.

## 13. A Consideration of Implications of the Working Group on the Organization of the SCRS that met in Madrid in February

Dr. Josu Santiago, the Chair of the SCRS, presented the conclusions and recommendations from the meeting. The critical need for capacity building and support for attendance at SCRS meetings was emphasized, particularly given the need to provide advice on the Commission's increasingly important areas of concern, such as the Ecosystem Approach to Fisheries Management.

The need was noted to provide advice that more fully considers uncertainty (such as the Kobe II Strategy Matrix) requiring the application of more complex methods such as fully integrated statistical modelling frameworks and Management Strategy Evaluation. The problem is, therefore, to ensure that there is sufficient capacity within the SCRS to apply such approaches. It was thought that there were two main ways to do this, e.g., recruit skilled staff at the Secretariat or to contract experts as required.

The benefits of both responses were discussed. Recruitment of staff at the Secretariat would ensure continuity across and between working groups but would require an agreement from the Commission. However, it was thought that for reasons of transparency, full participation by CPCs in working groups, would still be essential.

## 14. Consideration of Implications of the Future of ICCAT meeting in Madrid in May

Dr. Josu Santiago, the Chair of the SCRS, presented the conclusions and recommendations made to the Commission from the Meeting of the Working Group on the Future of ICCAT.

Important areas discussed were the needs to provide advice on the Precautionary Approach and an Ecosystem Approach on Fisheries Management. It was recognized that to provide advice on both areas requires greater consideration on issues such as the management of by-catch species and advice that more fully considers uncertainty.

## 15. Consideration of Implications of the Third Meeting of Tuna RFMOs held in July in La Jolla, USA

Dr. Josu Santiago, the Chair of the SCRS, presented the conclusions and recommendations of the meeting relating to the SCRS.

The importance to develop common data confidentiality rules and a draft protocol for data sharing was recognized. Therefore, the development of a protocol to specify the types of data to be shared, how these data can be used, and who can have access to these data, was recommended.

The importance of the Kobe II Strategy Matrix (K2SM) to communicate between stakeholders and to assist in the decision-making process was recognized as was the fact that substantial uncertainties still remain in the assessments. Therefore, it was recommended that the Scientific Committees and Bodies of the tRFMOs develop research activities to better quantify the uncertainty and understand how this uncertainty is reflected in the risk assessment inherent in the K2SM.

As it was also recognized that a Management Strategy Evaluation (MSE) process needs to be widely implemented in the tRFMOs in line with implementing a precautionary approach for tuna fisheries management, it is recommended that a Joint MSE Technical Working Group be created and that this Joint Working Group work electronically, in the first instance, in order to minimize the cost of its work. It was agreed that ICCAT take a leading role in this work.

## 16. Consideration of plans for future activities

### 16.1 Annual Work Plans

The rapporteurs summarized the 2012 Work Plans for the various Species Groups. These Plans were adopted and are attached as Appendix 4.

Regarding the tropical tunas proposal of implementing a large-scale tagging program in 2012 and beyond, the Committee considered the possibility of getting funds from the Directorate General for Development and Cooperation of the European Commission. In order to activate the procedure it was decided to create a task force among the tropical group members. With respect to the small tunas proposal, it was requested that the Secretariat explore alternative sources of funding for data collection and research of important local small tunas fisheries, particularly in developing countries. Côte d'Ivoire and Senegal expressed their support and willingness to participate in this research initiative. There was a general recommendation to support scientific quota allocations to support financially different research programs, with priority for the bluefin year program (GBYP). Norway expressed their favorable experience in this area and offered to share their expertise. The United States, Canada and the EU endorsed this recommendation.

### 16.2 Inter-sessional meetings proposed for 2012

Taking into account the assessments mandated by the Commission and the Committee's recommendations for research coordination, the proposed inter-sessional meetings for 2012 are shown as in Table 16.2. The

Committee noted that the schedule needs to maintain some flexibility in order to account for any changes that may result from the deliberations held by the Commission in November 2012 and the meetings scheduled by other RFMOs.

Depending on the decision of the Commission, the inter-sessional meetings next year will include the Methods Working Group and the Tropical Tunas Species Group in April 2012, the white marlin assessment in May, the Sharks Species Group meeting in June, the Working Group on Ecosystems in July, and the bluefin tuna stock assessment in early September. Portugal expressed its wish of holding the Shark Species Group meeting. The meeting will be held in the Algarve region.

Table 16.2 Proposed calendar of ICCAT scientific meetings in 2012.

## ICCAT MEETINGS 2012

* The tentative five days meeting could be extended two more days, before or after the current dates.

### 16.3 Date and place of the next meeting of the SCRS

The next meeting of the SCRS will be held in Madrid from the October 1 to 5, 2012; the Species Groups will meet from the September 24 to 29, 2012.

## 17. General recommendations to the Commission

The SCRS noted that attendance at inter-sessional meetings is becoming an increasing concern. During the last Atlantic swordfish and South Atlantic and Mediterranean albacore assessments the lack of scientists familiar with the analyses being present at the meeting and/or conducted in the previous assessment made it difficult to conduct and/or evaluate some of the analyses. This important issue was analyzed in detail by the Working Group on the Future Organization of the SCRS. Based on the result of these analyses, the Committee recommends that actions beyond encouraging participation in scientific meetings of CPC scientists and providing short-term training workshops should be further encouraged and supported with capacity building funds to involve developing economy scientists in the work of the SCRS. Actions such as supporting visiting scientist opportunities at national laboratories or the Secretariat could accelerate more participation and involvement in the work of SCRS. Broad participation in the SCRS by CPC national scientists is an important element in promoting scientific transparency in the methods, data, and assumptions used in development of scientific advice to the Commission. While capacity building funds have been used to encourage a broader attendance of scientists from developing economies, there is evidence that scientific contributions from all but a few developing economies are not improving to a measurable degree and additional actions are needed for improvement.

The Committee endorsed the recommendations of the working group on SCRS Organization. The Committee noted in particular, the following:

## Increase analytical and data base management support at the Secretariat

The recommendations for increased data base, analytical, and by-catch coordination support were endorsed by the Sub-Committee on Statistics and were recommended to Plenary. These positions should be included in the 2012 Budget of the Secretariat, but because the proposed budget was already circulated in July and only included the by-catch coordinator position, it presents a difficulty. The timing between preparation of the Budget and the identified needs of the SCRS needs to be better coordinated. The Committee recommended the SCRS Chair and Executive Secretary consult on procedures to avoid such difficulties.

## Quality assurance and transparency

The Committee endorsed the recommendations to use the data fund to contract help to develop stock assessment documentation during meetings and to invite experts from other tRFMOs to participate in our stock assessments.

### 17.1 General recommendations to the Commission that have financial implications

The acquisition of new biological information is necessary to reduce uncertainties in key biological parameters and processes that affect the outputs of the stock assessment models, such as growth, reproduction, stock delimitation and stock mixing. Fisheries-independent information, such as tagging operations or aerial/acoustic surveys, has been also shown, for many pelagic exploited fish species of various oceans, to be crucial to get better estimates of natural and fishing mortality and to track trends in population size; and thereby to provide more robust and more precise scientific advice to the commission. Finally, more sophisticated (but also more demanding) modeling approaches are increasingly used in RFMOs while the Kobe process further encourages original approaches, such as the Management Strategy Evaluation to better take into account for uncertainties in the scientific advice. The establishment of scientific quota in several fisheries worldwide, such as the small pelagic fisheries of the North Atlantic, contributed to generate higher revenue for the fisheries.

All these needs are fully justified from a scientific and management viewpoint. Because such needs apply for all the tuna and tuna-like species, the SCRS recently requested funding of large-scale research program for several species, such as bluefin tuna, albacore tuna, billfish and the three major tropical tuna species. However, research programmes have also a high cost and can hardly be supported by CPCs if they are planned at the same time. Furthermore, the development of fisheries-independent surveys and original modeling approaches imply continuous effort over several years to be fruitful, so that it is crucial to secure funding over the whole duration of the research program. Finally, it worth noting that large research programme will be attractive to academic scientists and could thus contribute to the strengthening and the renewal of the SCRS.

For all these reasons the SCRS recommends that the Commission consider the possibility of establishing a "scientific TAC" for each tuna and tuna-like species for which a TAC is already implemented and for which a large-scale research programme is needed. Such a scientific quota would be part of the TAC but would not exceed a small percentage of this TAC. It could further be managed by the ICCAT secretariat which could, according some terms of reference, sell it on the market at the best offering fisheries entity during an annual official auction or subcontract a fishing vessel to sell the catch on the market. The modalities of such scientific quota need, however, to be deeper investigated and could be studied by the SCRS in 2012, according to existing scientific TAC in other fisheries worldwide.

## Albacore

The Committee reinforces the recommendation of initiating and focusing on an albacore research program for North Atlantic albacore, given the large uncertainties identified by the Committee and in the light of the observed changes in availability of the stock in the northeast Atlantic during the last few years. The research plan will be focused on three main research areas: biology and ecology, fisheries data, and management advice during a four-year period. Detailed research aims are presented in Ortíz de Zárate (2011). The requested funds to develop this research plan have been estimated at a cost of 4.3 million Euros. Details of the economic plan are provided in the Albacore Work Plan (Appendix 4).

## Billfishes

Noting the misidentification problems between white marlin, roundscale and longbill spearfishes, the SCRS recommended conducting an Atlantic-wide survey of WHM-RSF-SPF distribution and abundance with the collaboration of CPCs with fleets covering the entire Atlantic, particularly in the eastern and southwestern Atlantic fishing areas.

The Committee strongly recommended that the Commission provide additional funding (15K Euros) to the Enhanced Billfish Research Program for a genetic study in order to accelerate the data acquisition and analysis for separating white marlin from spearfishes to be undertaken in the immediate future.

## Bluefin tuna

The SCRS strongly supports the Atlantic-wide Research Programme for Bluefin Tuna (GBYP) and the continued acquisition of new biological information and fisheries-independent information as well as to investigate new and original modeling approaches. Without continued effort in these areas, it is very unlikely that the SCRS will be able to reduce the uncertainty in its scientific advice.

The SCRS recommends that the Commission and all CPCs concerned reaffirm their commitments to GBYP by:

- Developing a funding schedule by which CPCs may calculate their voluntary contributions;
- Ensuring assistance for the necessary permits concerning the GBYP activities in their territorial waters or airspace;
- Providing the necessary contacts at the national level for ensuring the regular development of the GBYP;
- Providing official derogations to allow the sampling of fish below the minimum size limit, the use of any type of fishing gear and the possibility of fishing even during the closed fishing season.
- Implementing a "research mortality allowance" up to 20 t for incidental mortality of bluefin tuna during GBYP conventional tagging and biological sampling programmes. Those dead fish could not be sold.

The development of fisheries-independent surveys and original modeling approaches imply continuous effort over several years to a decade to be fruitful and allow us to detect trend in population size. Therefore, it is crucial to secure funding over several consecutive years to avoid any potential waste of money and effort due to a premature stop in the funding of the scientific operations.

To do so, the SCRS strongly encourages the Commission to consider a research TAC set aside to help fund the GBYP for the coming year. A research allocation up to of 50 t could be quite beneficial in supporting the GBYP research enterprise while reducing the necessity for voluntary contributions for the program. For 2013 and thereafter, such a scientific TAC could fully fund the GBYP (so that no voluntary contributions will be needed) if the allocation may reach up to $320 \mathrm{t} /$ year (about $2.5 \%$ of the current TAC). This scientific quota could be managed by ICCAT Secretariat which could, for instance, sell it on the market at the best offering fisheries
entity during an annual official auction or subcontract a fishing vessel to sell the catch on the market. The modalities of such scientific quota need, however, to be deeper investigated and could be studied by the GBYP steering committee or the SCRS, according to existing scientific TAC in other fisheries worldwide.

## Tropical tunas

1. The Committee encourages the continuation of the cooperation with Ghanaian scientists. A proposal for collaboration between Ghanaian and IRD scientists is presented as an Addendum to the Tropical Tuna Species Group Work Plan for 2012 (Appendix 4).
2. The Committee reiterates the importance of the implementation of a large-scale tagging program for tropical tuna species in 2012 and beyond (see Addendum 2 to Appendix 5 of the 2010 SCRS Report) (ICCAT, 2011).

## Sharks

The Committee recommended incorporating the description of the six shark species that have been included in recent Recommendations (ALV, BTH, OCS, SPL, SPZ, SPM) in Chapter 2 of the ICCAT Manual in the bycatch species section (Appendix 4).

## Sub-Committee on Ecosystems

The Committee noted that the By-catch Coordinator position remains unfilled and strongly recommends that this position be recruited promptly.

## Small tunas

The Committee recommends the establishment of an ICCAT Year Research Programme for small tuna species as detailed in the Addendum to the Small Tunas 2012 Work Plan (Appendix 4).

### 17.2 Other recommendations

## Albacore

The SCRS recommended continuing the work towards integrating the various studies relating life history parameters and ecology for Mediterranean albacore.

## Billfishes

The SCRS recommended that the study on age and growth of blue marlin continue, stressing the need to include in the study anal spine sections from large specimens in subtropical and temperate areas.

The SCRS recognized the complexity of white marlin reported catches where historical catches may comprise a mixture of species, like roundscale spearfish (RSP) and longbill spearfish (SPF) in addition to white marlin. Therefore, the Committee recommended that the white marlin stock assessment to be conducted in 2012 be considered as mixed species stock assessment.

In noting that estimation of relative abundance indices is always best done at the highest spatiotemporal resolution warranted by the available data, the SCRS recommended that all CPCs, and especially those that have important catches of white marlin, provide updated relative abundance indices obtained from such high resolution CPUE data and also to take into consideration the effect of current regulations in the standardization process. For instance, when only information on retained fish is available, the effect of implementing regulations requiring the release of live fish from longlines should be accounted for, such as by developing separate indices before-after implementation.

The SCRS recommended that the surplus production models conducted in the 2000 white marlin stock assessment be updated in the 2012 stock assessment meeting.

## Bluefin tuna

The Committee reiterated that it is essential to obtain representative samples of otoliths and other tissues from all major fisheries in all areas. Such collections will provide direct estimates of the age composition of the catch
(avoiding the biases associated with determining age from size), direct estimates of the stock of origin (a key factor to improve our ability to conduct mixing analyses) and will help in verifying current assumptions concerning age-at-maturity and fecundity-at-age. This activity should be coordinated with the GBYP.

The SCRS recommends that the Secretariat conduct cross-validation of the ICCAT bluefin tuna size database.
Pilot studies using dual camera systems to retrieve the size of fish at the location of the catch (or close to) were presented at the SCRS in 2011. The results being encouraging, the SCRS strongly recommends that the CPCs carry on these studies, so that stereoscopic camera systems become operational as soon as possible.

In order to improve the utility of BCD for scientific use, the Commission should implement electronic reporting forms and formats for transmission of the data to the Secretariat in order to improve the availability of complete data to the SCRS for cross-validation.

## Tropical tunas

Several recommendations concerning improvement of research and the statistics of tropical tunas can be found in the Detailed Report of the 2011 Tropical Tuna Species Group Inter-sessional Meeting on the Ghanaian Statistics Analysis (Phase II) (SCRS/2011/016) and in the Detailed Report of the 2011 ICCAT Yellowfin Tuna Stock Assessment Session (SCRS/2011/020).

## Sharks

The SCRS is pleased with the conservation and management measures adopted by the Commission in the last two years regarding the species classified as the most vulnerable in the last ecological risk assessment and for which no data were presented (bigeye thresher, oceanic whitetip and hammerhead). At the same time, the SCRS expressed its concern that no conservation and management measures have been adopted up to now on silky shark (Carcharhinus falciformis), classified in the ERA among the most vulnerable species. Consequently, the SCRS recommended that adequate conservation and management measures, similar to those adopted for the aforementioned species also be adopted for silky shark.

The Committee recommended that observers be allowed to collect biological samples (vertebrae, tissues, reproductive tracts, stomachs) from those species whose retention is prohibited by current regulations. The Committee recommended that CPCs explore methods to estimate the catches of sharks in the purse seine and artisanal fisheries.

## Sub-Committee on Ecosystems

1. The Committee recommends that the Secretariat attempt to collate user manuals or protocols describing data collection from CPC observer programs. Also, an attempt should be made to identify historical changes to the data collection protocols that might complicate data analyses and interpretation.
2. The Committee recommends that guidelines for the presentation and analysis of by-catch statistics be developed in conjunction with the Working Group of Stock Assessment Methods (WGSAM) and that these guidelines be made available as part of the ICCAT Manual. Furthermore, the Sub-Committee on EcoSystems should work with WGSAM to evaluate how these data can be used as part of a risk management advice framework.

## Assessments and methods

1. Meta-analysis and methods for informing key parameters: It was recommended to pursue Robin Hood approaches in order to evaluate their use for providing management advice and continue pursuing metaanalyses but identifying biases due to model assumptions. The Robin Hood approach is where stock assessments are conducted for multiple stocks at the same time. This allows information from data-rich stock assessments, e.g. trends in fishing mortality, values for parameters of selectivity functions and biological parameters to be provided to data-poor assessments. This leads to stock assessments for the most data-poor stocks being informed by those for the most data-rich stocks, i.e. taking from the rich and giving to the poor (Punt et al., 2011).
2. Harvest Control Rules: Simulated HCRs should be based on the advice provided by the 2010 Working Group Stock on Assessment Methods and Appendix 6 of the 2011 Future of ICCAT meeting report unless shown otherwise. Alternative harvest control rules, including empirical rules (Anon. 2011g) should be developed and evaluated, although it thought that these will supplement rather than replace more comprehensive analytical harvest control rules. Management Strategy Evaluation should be a participative approach involving all stakeholders, from scientists to managers, the industry and the fishing communities. It should be developed for ICCAT tuna fisheries and it is recommended that MSE be actively pursued to develop robust management practices which can achieve the Convention objectives within time frames and tolerable risks that the Commission decides appropriate. As part of this process, it is necessary to work toward a full characterization of scientific uncertainty in stock status to improve estimates of risk.

## Sub-Committee on Statistics

The Committee recommended that VMS signals should be reported at no more than two hour interval. Furthermore, the Committee recommended requesting VMS data from other ICCAT fisheries and from VMS associated to FADs.

During the Yellowfin Stock Assessment Session, Japan submitted revised CAS of YFT-LL for the period 19952010. Documentation supporting the review of the data was also provided during the yellowfin assessment in an SCRS document. The Committee inquired if the newly applied methodology could be extended to other species caught by the Japanese LL fleet and recommended that Japanese scientists consider if the methodology used for yellowfin tuna is also appropriate for other species.

The Committee agreed with the recommendation from the Billfish Species Group to develop ID cards for Istiophorids.

The Committee supported the Secretariat's proposal to contract out the development of the LL gear chapter of the ICCAT Manual. The Committee agreed with the recommendations to update the description of white marlin and spearfishes (RSP, Tetrapturus georgei, SPF, Tetrapturus pfluegeri) and to expand the description of several shark species to the corresponding chapter.

The Committee endorsed the recommendations of the Ghanaian statistics Working Group.
The Committee discussed and endorsed the recommendation to use market-based information to validate logbook catch reports and recommended expanding such approaches to other species, when such information is available.

The Committee reiterated that there is a need to quantify the quality of the information reported and the quality/representativeness of size samples from different fisheries is a question that fits within this issue. A $10 \%$ sampling fraction could be adopted as a general rule that could be revised on a fisheries basis. It was also indicated that for the future analysis to better characterize the level of sampling that will provide information to improve management recommendations should be conducted.

The Sub-Committee on Statistics discussed the need of forms to submit seabird, sea turtle, other by-catch, and observer data. It is expected that this task will be taken by the by-catch coordinator. The Secretariat indicated that it only received observer data from one CPC. The Committee recommended that CPCs report observer data to help the Secretariat to develop electronic forms for the submission of this type of data. The Committee approved the Secretariat's recommendation of adding spearfish to the list of main ICCAT species.

## 18. Responses to Commission's requests

### 18.1 Develop a Limit Reference Point (LRP) for the North Atlantic swordfish stock Rec. [10-02]

Rec. [10-02] paragraph 6 requests the SCRS to develop a Limit Reference Point (LRP) for the North Atlantic swordfish stock in advance of the next assessment of North Atlantic swordfish. On the basis of the LRP established by the Committee, future decisions on management shall include a measure that would trigger a rebuilding plan, should the biomass decrease to a level approaching the defined LRP.

An updated framework model for evaluation of biomass based limit reference points for the north Atlantic swordfish stock was reviewed by the Committee (Pons and Domingo, 2011). The objective was to determine the variability on biomass due to the particular biological characteristics of the stock.

In the case of North Atlantic, only the variability associated with the stock-recruitment (SRR) assumption as was considered as the source of "normal" variations of the total biomass. Preliminary results indicated that, at this level of variation under equilibrium age structure conditions $80 \%$ of the northern swordfish biomass is expected to be between -0.20 and +0.25 fraction of the reference biomass. Using as an example, a biomass limit point ( $\mathrm{B}_{\lim }$ ) defined as $\mathrm{B}_{\lim }=\mathrm{B}_{\text {MSY }} *(1-\mathrm{M})$, there is a low probability of $\mathrm{B}<\mathrm{B}_{\lim }(<5 \%)$, if the stock is fished at the $\mathrm{F}_{\text {ref }}$ reference harvest rate. This probability would represent the changes of false negatives (trigger a response, when actually the $B$ is just responding to natural variations). The results also indicated that the response of the recovery once an overexploitation is realized can take several years, even at relatively moderate overfishing levels when its duration continues over several years.

It is recommended to conduct further evaluations of biomass based reference limit points, to include alternative stock-recruitment hypothesis, and different selectivity patterns. Consideration of alternative biomass limits, based on percentiles of other targets levels ( $\mathrm{B}_{\text {MSY }} \%$ ) is also advised.

Once candidate limit reference points are identified, SCRS/2011/195 describes a simulation framework that will allow the evaluation of their performance (i.e., how well management objectives are met), and their robustness to uncertainty.

The SCRS plans to continue with this work towards identifying and testing of a limit reference point prior to the next assessment (proposed for 2013), and this task is identified in the Species Group Work Plan. Finally, the SCRS noted that development of a limit reference point which increased the probability of remaining within the rebuilt condition for North Atlantic swordfish would be fully consistent with the principles of decision-making considered by the 2011 Working Group of the Future of ICCAT (Figure 18.1).

Figure 18.1. Principles of decision-making for ICCAT conservation and management measures (Working Group on the Future of ICCAT Meeting, 2011).

### 18.2 Review of North Atlantic swordfish data requested under [Rec. 10-02]

[Rec. 10-02] paragraph 12 calls for the SCRS to provide an evaluation of the best available data submitted by all CPCs. Those data should include catch, catch at size, location and month of capture on the smallest scale
possible, as determined by the SCRS. The data submitted shall be for broadest range of age classes possible, consistent with minimum size restrictions, and by sex when possible. The data shall also include discards and effort statistics, even when no analytical stock assessment is scheduled.

While no specific responses to this request were submitted by CPCs, the SCRS tabulated the information currently available to the SCRS for stock assessment purposes (see Table 2, Report of the Sub-Committee on Statistics). The information is ranked for the main CPC/gear combinations by percent catch (averaged over 1990-2009), and to make the information manageable, only the combinations comprising the top $95 \%$ of landings is shown. The summary indicates an improving trend in the availability of catch and effort information, but provides no indication of the quality or completeness of the available data (see also the Report of the SubCommittee on Statistics). Over the recent past (2000-2010), CPCs providing information on dead discards include USA, Canada and Japan for the North Atlantic stock.

### 18.3 Exploration of operationally viable technologies and methodologies for determining the size and biomass at the points of capture and caging [Rec. 10-04]

The 2010 Recommendation amending previous Recommendations by ICCAT to Establish a Multi-annual Recovery Plan for Bluefin Tuna in the eastern Atlantic and Mediterranean [Rec. 10-04] requests the CPCs to initiate pilot studies on how to better estimate both the number and weight of bluefin tuna at the point of capture and caging including through the use of stereoscopic systems and report the results to the SCRS.

During the BFT Species Group held in September 2010, four SCRS documents regarding the use of stereoscopic camera systems were presented to the SCRS (SCRS/2011/173, SCRS/2011/189, SCRS/2011/190 and SCRS/2011/191). These documents describe some work in progress on board of Mediterranean cages in 2011. The estimates of fork length remain incomplete because of a few technical issues that remain to be solved. However, the first results are encouraging and confirm the potential of stereoscopic camera to recover the length composition of the fish that are transferred alive into cages. The SCRS strongly encourages the CPCs to carry on and complete these studies in 2012, so that stereoscopic camera systems become operational as soon as possible.

While the cages do not correspond to the exact points of captures, the information from cages may be, however, adequate to reconstruct the size composition of the catch if the measurements are performed at the arrival of the towing vessel. Trials with stereoscopic camera on board of fishing vessel have been also investigated in 2011, but the results of these operations were not provided to the SCRS.

### 18.4 Reporting on the scientific aspects of the national observer programmes on the basis of the information provided by CPC [Rec. 10-04] [Rec. 10-10]

18.4.1 Reporting on the bluefin scientific data coverage level achieved by each Contracting Party observer program [Rec. 10-04]

Rec. 10-04 establishes obligations to CPCs to conduct national observer programs to ensure specific observation coverage on vessels active in the bluefin tuna fishery. This provision affects purse seines equal or less than 24 m in 2011 ( 20 m in 2012), pelagic trawlers (over 15 m ), longliners (over 15 m ) and baitboats (over 15 m ), tuna traps and towing vessels.

The main work of the observers on board is related to compliance activities but, in addition, when required by the Commission and based on the instructions of the SCRS, the observers could carry out scientific work, such collecting Task II data.

The SCRS has been requested to report on the coverage level achieved by each CPC and to provide a summary of the data collected and any relevant findings associated with the data. The SCRS has been also requested to provide any recommendations to improve the effectiveness of CPC observer programmes.

The Secretariat informed that few CPCs had provided information on their national observer programs. The information received presented insufficient degree of detail, except for China and Japan. The SCRS was aware that more CPCs had observer programs in place but details hadn't been made available to the Secretariat. Therefore due to the limitation of the data provided, the SCRS didn't have enough elements to conduct a detailed analysis on the coverage level achieved or on any relevant findings associated with the national observers data.

The SCRS recommends that the CPCs transmit as soon as possible all scientific information of the 2011 national observer programmes to the national scientists. If provided in due time, the national scientists could analyze this information and transmit all relevant processed data to the ICCAT Secretariat, according to the deadline of the 2012 bluefin tuna Work Plan.
18.4.2 Reporting Information on national observer programs based on the information provided by CPCs [Rec.10-10]

In response to the Commission's request 18.4, the Secretariat has received the responses from 12 CPCs so far (as of September 15, 2011). To date, only a low proportion of responses that could have been submitted have yet been received by the Secretariat. The level of detail and information provided was quite variable among CPCs. The Committee reviewed the information provided and recommended the Secretariat elaborate a questionnaire form to distribute to all CPCs to facilitate gathering the information requested under Rec 10-10.

### 18.5 Completing the sharks identification guide [Rec. 10-06]

The second part of the identification sheets for Atlantic shark species was presented to the Committee. The new guide is pending final revision and will soon be available in the three official ICCAT languages.

### 18.6 Evaluating the information provided by CPCs on alternative scientific monitoring approach to observer program to apply in vessels less than 15 m . [Rec. 10-10]

As of the start of the meeting of the Committee only partial information from one Contracting Party had been received on alternative methods for the collection of detailed information on vessels less than 15 m , which did not allow the Committee to carry out an assessment and prepare a response to the Commission regarding this matter.

### 18.7 Continuation of the evaluation of data elements pursuant to [Rec. 05-09]

In response to the Commission Rec. [05-09], the SCRS through the Sub-Committee on Statistics and the Secretariat, prepare each year a summary of the impact on stock assessment and evaluations from the lack of, deficiencies and limitations of data available for the Working Groups. Since 2007, a questionnaire has been distributed to the Rapporteurs of each Species Group that had an assessment or data preparatory meeting during the year. The questionnaire attempts to collect the working group data availability and impact on their analysis, as well specific recommendations to improve their assessment work. During 2011, several ICCAT species were assessed: blue marlin, southern and Mediterranean albacore, and yellowfin tuna. Document SCRS/2011/207 includes the response to the questionnaires by the Chairs of the respective Working Groups in 2011.

### 18.8 Response to the Commission Regarding Rec. 10-09

During the 2011 Species Groups meetings the Sub-Committee on Ecosystems met and reviewed progress toward meeting the data submission requirements outlined in Rec.10-09.

In 2011, the Sub-Committee on Ecosystems reviewed five working papers and two presentations addressing turtle by-catch in the Convention area. As with seabirds, factors were identified contributing to the number of encounters along with effective mitigation measures. The Group also viewed documentation geared towards educating fishers on proper gear removal and handling techniques. A description of a capacity building program, the Trans Atlantic Leatherback Conservation Initiative Program, was provided.

To expedite the evaluation of the impact of ICCAT fisheries on sea turtle populations [Rec. 10-09], the ICCAT Secretariat, the SCRS Chair and the Convener of the Sub-Committee on Ecosystems developed a call for tenders to hire a Sea Turtle Expert. The contract has been awarded and work is scheduled to begin in the first quarter of 2012. The contract is for a 6 months term and one of the final deliverables will be the database containing the information needed to conduct the impact assessment. The Sea Turtle Expert, through the Secretariat, will also coordinate efforts to identify and contact national scientists with expertise in sea turtles, by-catch estimation procedures or analytical techniques used to conduct impact assessments on by-catch species. The SubCommittee on Ecosystems will coordinate with the Sea Turtle Expert to facilitate this process.

The Sub-Committee on Ecosystems also established a work plan for activities in 2012 relating to Rec. 10-09. During 2012, the Sea Turtle Expert, in cooperation with the Sub-Committee on Ecosystems and the Secretariat, will identify and compile the following:

1. Sea turtle by-catch data sources
2. Gaps in knowledge
3. Methodologies used to extrapolate total by-catch using data from the reporting fleets
4. Methods to estimate post-release mortality.
5. Impact assessment methodologies that may appropriate to implement given the available data.

The Sub-Committee will meet in 2012 to review this information and make recommendations with regard to the utility of the methodologies described in items 3-5. National scientists identified by the CPCs and selected by the Sea Turtle Expert as possessing expertise in these methodologies will be encouraged to attend.

## 19. Other matters

The issue of having two rapporteurs for the Sub-Committee on Ecosystems was discussed and it was agreed to have a rapporteur devoted on ecosystem issues and a second rapporteur focused on by-catch would help in addressing the increasing workload of this Sub-Committee.

At the Kobe III meeting it was agreed to create a joint Management Strategy Evaluation (MSE) working group and it was agreed that ICCAT would take the lead on this increasingly important approach for providing management advice. This would be handled within the Working Group on Stock Assessment Methods.

Although southern bluefin tuna is managed by CCSBT, it is found within the ICCAT Convention area. In the past, the SCRS was informed of the results of the assessment conducted by the CCSBT. However, in the most recent years, the SCRS decided it would no longer deal with issues related to southern bluefin leaving this to CCSBT, although it was felt that understanding the dynamics of southern bluefin was therefore important for the SCRS.

## 20. Adoption of the report and closure

The United States thanked the Chair of the SCRS for his guidance throughout the meeting and hoped he would be here to guide the SCRS through many more with the same skill.

The Chair responded by saying that chairing the SCRS was a great honour but also a great responsibility. He thanked the members of the Committee for their hard work not only during this week but also throughout the whole year. Dr. Santiago thanked everyone for their support and singled out Dr. Gerry Scott, the previous Chair of the SCRS. The SCRS Chair also expressed his appreciation for the support of the Secretariat as well as his thanks to the Interpreters who have a key task in allowing us all to understand each other. Finally, he emphasized that we now have the responsibility of giving our advice to the Commission.

The Executive Secretary then closed the meeting and thanked the chair for his guidance and leadership through this his first meeting. He then thanked all the members of the Committee and noted that there is always something new that crops up that stimulates the occasion. Mr. Meski thanked the Committee, the Secretariat and the Interpreters for their hard work this week on behalf of the Commission and wished everybody a safe journey home.

The Report of the 2011 SCRS meeting was adopted.
The 2011 Meeting of the SCRS was adjourned.

## AGENDA

1. Opening of the meeting
2. Adoption of Agenda and arrangements for the meeting
3. Introduction of Contracting Party delegations
4. Introduction and admission of observers
5. Admission of scientific documents
6. Report of Secretariat activities in research and statistics
7. Review of national fisheries and research programs
8. Executive Summaries on species:

YFT-Yellowfin, BET-Bigeye, SKJ-Skipjack, ALB-Albacore, BFT-Bluefin, BIL-Billfishes, SAI-Sailfish, SWO-Atl. Swordfish, SWO-Med. Swordfish, SMT-Small Tunas, SHK-Sharks
9. Report of inter-sessional meetings
9.1 Workshop on the use of R tools in the data preparatory work ICCAT-SCRS
9.2 Working Group on the Organization of the SCRS
9.3 2011 Blue marlin stock assessment session and white marlin data preparatory meeting
9.4 Inter-Sessional Meeting of the Sub-Committee on Ecosystems
9.5 Tropical tuna species group inter-sessional meeting on the Ghanaian statistics analysis (Phase II)
9.6 Sharks data preparatory meeting to apply Ecological Risk Analysis
9.7 Joint Meeting of the ICCAT Working Group on Stock Assessment Methods and the bluefin tuna species group to analyze assessment methods developed under the GBYP and electronic tagging
9.8 South Atlantic albacore and Mediterranean albacore assessment sessions
9.9 Yellowfin stock assessment session
10. Report of Special Research Programs
10.1 Atlantic Wide Research Programme for Bluefin tuna (GBYP)
10.1.1 GBYP working group on the aerial surveys analysis, conventional tagging and biological sampling
10.1.2 Symposium on Trap Fishery for Bluefin Tuna
10.1.3 Working Group to analyze assessment methods developed under the GBYP
10.2 Enhanced Research Program for Billfish
11. Report of the Sub-Committee on Statistics
12. Report of the Sub-Committee on Ecosystems
13. A Consideration of Implications of the "Working Group on the Organization of the SCRS" met in Madrid in February.
14. A Consideration of Implications of the "Future of ICCAT" meeting in Madrid this May
15. A Consideration of Implications of the third meeting of Tuna RFMOs held in July in La Jolla, USA.
16. Consideration of plans for future activities
16.1 Inter-sessional meetings proposed for 2012
16.2 Date and place of the next meeting of the SCRS
17. General recommendations to the Commission
17.1 General recommendations to the Commission that have financial implications
17.2 Other recommendations
18. Responses to Commission's requests
18.1 Develop a Limit Reference Point (LRP) for the North Atlantic swordfish stock Rec. [10-02]
18.2 Review of North Atlantic swordfish data requested under [Rec. 10-02]
18.3 Exploring operationally viable technologies and methodologies for determining the size and biomass at the points of capture and caging [Rec. 10-04]
18.4 Reporting on the scientific aspects of the national observer programmes on the basis of the information provided by CPC [Rec. 10-04]
18.5 Completing the sharks identification guide [Rec. 10-06]
18.6 Evaluating the information provided by CPCs on alternative scientific monitoring approach to observer program to apply in vessels less than 15 m . [Rec. 10-10]
18.7 Continuation of the evaluation of data elements pursuant to [Rec. 05-09]
18.8 Response to the Commission Regarding Rec. 10-09
19. Other matters
20. Adoption of report and closure

## LIST OF PARTICIPANTS

## CONTRACTING PARTIES

## SCRS Chairman

## Santiago Burrutxaga, Josu

SCRS Chairman - Head of Tuna Research Area, AZTI-Tecnalia, Txatxarramendi z/g, 48395 Sukarrieta (Bizkaia), Spain
Tel: +34 946574000 (Ext. 497); 664303631, Fax: +34 946572555 , E-Mail: jsantiago@azti.es

## LIST OF 2011 SCRS DOCUMENTS

| Number | Title | Author(s) |
| :---: | :--- | :--- | :--- |
| SCRS/2011/011 | Report of the GBYP Working Group on the Aerial <br> Surveys Analysis, Conventional Tagging and <br> Biological Sampling (Madrid, Spain - February 14 to | Anonymous |
| 18, 2011). |  |  |

|  | SCRS/2011/026 | Captura, distribución y composición de tallas del aguja <br> blanca, Tetrapturus albidus, observada en la flota de <br> palangre uruguaya (1998-2010), | Domingo A., Forselledo, <br> R. and Pons, M. |
| :--- | :--- | :--- | :--- |
| SCRS/2011/027 | Indice de abundancia estandarizado de las capturas de <br> atún rojo (Thunnus thynnus) obtenidas por las <br> almadrabas españolas y marroquíes. | Abid, N., Ortiz de <br> Srbina, J.M. and de la <br> SCRS/2011/028 | Annual mean weight of bluefin tuna (Thunnus <br> thunnus) caught by the traps in the south of Spain <br> between 1914-2010. |
| SCRS.M. and Velasco, M. |  |  |  |

| SCRS/2011/045 | Standardization of blue marlin (Makaira nigricans) CPUE for the Taiwanese longline fishery in the Atlantic Ocean. | Sun, C-L., Su. N-J. and Yeh, S-Z. |
| :---: | :---: | :---: |
| SCRS/2011/046 | Possible stock production models for blue marlin in the Atlantic Ocean up to 2009. | Schirripa, M. and Babcock, E. |
| SCRS/2011/047 | An evaluation of methods for standardizing catch rates of highly migratory by-catch species. | Lynch, P.D., Shertzer, K.W., and Latour, R.J. |
| SCRS/2011/048 | Preliminary analyses of simulated longline Atlantic blue marlin CPUE with HBS and generalized linear models. | Goodyear, C.P. and Bigelow, K.A. |
| SCRS/2011/049 | Length composition and spatiotemporal distribution of blue marlin (Makaira nigricans) in the South Atlantic Ocean. | Frédou, T., Frédou, F.L., Hazin, F.H.V. and Travassos, P. |
| SCRS/2011/050 | Standardized CPUE series of blue marlin and white marlins caught by Brazilian tuna longline fisheries in the southwestern Atlantic Ocean (1980-2010). | Hazin, H.G., Mourato, B., Hazin, F., Carvalho, F., Frédou, T., Travassos, P. and Pacheco J.C. |
| SCRS/2011/051 | Inter-annual variability in the proportion of roundscale spearfish (Tetrapturus georgii) and white marlin (Kajikia albida) in the western North Atlantic Ocean. | Graves, J.E. and McDowell, J.R. |
| SCRS/2011/052 | Preliminary studies on the possible influence of environmental factors on the catchability of the Blue marlins off the western coast of Ghana. | Bannerman, P. |
| SCRS/2011/053 | Cory's shearwater by-catch in the Mediterranean Spanish commercial longline fisheries: Implications for conservation. | Báez, J.C., GarcíaBarcelona, S., Mendoza, M., Ortiz de Urbina, J.M., Real, R. and Macías, D. |
| SCRS/2011/054 | An example application of the SEMIPRO (Spatial Explicit Multispecies Integrated Production model) to Atlantic tuna and billfish. | Carruthers, T. and McAllister, M. |
| SCRS/2011/055 | Optimizing the spatial distribution of effort to achieve management goals in a multi-species, multi-fleet fishery. | Carruthers, T. and McAllister, M. |
| SCRS/2011/056 | Pelagic longline seabird by-catch mitigation measures: update of current research. | Anderson, O.R.J. |
| SCRS/2011/057 | Movements of juvenile loggerhead turtles in the southwestern Atlantic Ocean. | Barceló, C., <br> Domingo, A., Miller, P., Ortega, L., Giffoni, B., Sales, G., <br> McNaughton, L., Marcovaldi, M., Heppell, S.S., Swimmer, Y. |
| SCRS/2011/058 | Setting deeper, catching fewer? Sea turtle by-catch on deep set pelagic longlines in Uruguayan waters. | Miller, P., Pons, M., Domingo, A. |
| SCRS/2011/059 | " J " hooks vs. "C" hooks in the Uruguayan monofilament longline fishery. | Domingo, A., Pons, M., Miller, P., Barceló, C., Jiménez, S., Swimmer, Y. |

| SCRS/2011/060 | Spatio-temporal correlation between leatherback turtles and industrial fisheries in the Atlantic Ocean. | Fossette, S., Coyne, M.S., Augowet, E., Broderick, A.C., Chacon, D., Domingo, A., Eckert, S.A., Vans, D., Felix, M.L., Formia, A., Godley, B.J., Hays, G.C., Kelle, L., LópezMendilaharsu, M., Luschi, P., Miller, P., Nalovic, M.A., Nougessono ,S., NSafou, M., Parnell, R.J., Prosdocimi, L., Sounguet, G.P., Turny, A., Verhage, B., Witt, M.J., Georges, J-Y. |
| :---: | :---: | :---: |
| SCRS/2011/061 | By-catch susceptibility in pelagic longline fisheries: Are albatrosses affected by the diving behavior of medium-sized petrels? | Jiménez, S., Abreu, M., Brazeiro, A., Domingo, A. |
| SCRS/2011/062 | Japanese activity for development of seabird by-catch mitigation measure and its scientific evaluation in pelagic longline fishery. | Ochi, D. |
| SCRS/2011/063 | A simulation framework to assess observer coverage for valuable fishes in Japanese observer data. | Katsumata, N., Ochi, D., Inoue, Y., Minami, H. and Yokawa, K. |
| SCRS/2011/064 | Preliminary Report of 2010 Weighted Branchline Trials in the Tuna Joint Venture Fishery in the South African EEZ. | Melvin, E., Guy, T. and Sato, N. |
| SCRS/2011/065 | Distribution of seabird by-catch using data collected by Japanese observers in 1997-2009 in the ICCAT area. | Inoue, Y., Yokawa K., Minami, H., Ochi, D., Sato, N. and Katsumata,N. |
| SCRS/2011/066 | The effect of leaded swivel position and light toriline on bird attack rates in Brazilian pelagic longline. | Gianuca, D., Peppes, F., César, J.H. and Neves ,T. |
| SCRS/2011/067 | Testing new designs of fish drifting fish aggregating device (DFAD) in eastern Atlantic to reduce turtle and shark mortality. | Franco, J., Moreno, G., Lopez. J., and Sancristobal, I. |
| SCRS/2011/068 | Review of actions by Brazil in meeting the BYC $10-$ 09 and FAO Guidelines to reduce sea turtle mortality in fishing operations. | de Oliveira Leite, Jr. N., Giffoni, B., Niemeyer Fiedler, F. and Sales, G. |
| SCRS/2011/069 | Données historiques sur les anciennes madragues françaises de Méditerranée. | Faruggio, E. |
| SCRS/2011/070 | Historical bluefin tuna catches from southern Portugal traps. | Pereira, J. |
| SCRS/2011/071 | Bluefin tuna imported to Portugal from Moroccan traps. | Pereira, J. |
| SCRS/2011/072 | Les usines de salaison de poisson dans le Maroc antique. | Habibi, M. |
| SCRS/2011/073 | The gold mine from the Atlantic bluefin tuna trap fisheries . | Fromentin, J.M. and Farrugio, H. |
| SCRS/2011/074 | Western Atlantic bluefin tuna trap fisheries. | Dean, J.M., <br> Andrushchenko, I. and Neilson, J. |

| SCRS/2011/075 | Long term analysis (1990-2010) of the catches of the <br> Atlantic Bluefin tuna (Thunnus thynnus) from the <br> traditional trap fisheries of Sardinia. | Addis, P., Secci, M., <br> Locci, I., Sabatini, A. and <br> Cau, A. |  |
| :--- | :--- | :--- | :--- |
| SCRS/2011/076 | Social, cultural and basic economic analysis of the <br> trap fishery of Sardinia: First step towards | Addis, P., Secci, M., <br> Locci, I., Cannas, R. and <br> parameterization. | Cau A. |
| SCRS/2011/077 | Harvesting, handling practices and processing of <br> bluefin tuna captured in the trap fishery: Possible <br> effects on the flesh quality. | Addis, P., Secci, M., <br> Locci, I. and Cau, A. |  |
| SCRS/2011/078 | Las almadrabas de la costa andaluza bajo el dominio <br> de la casa ducal de Medina Idonia. Su tipología, sus | García García, F. |  |

| SCRS/2011/094 | Ítems alimenticios del tiburón tigre (Galeocerdo cuvier) en aguas sub-tropicales del Océano Atlántico Sur Occidental. | Miller, P. and Domingo, A. |
| :---: | :---: | :---: |
| SCRS/2011/095 | Aves en la dieta del tiburón azul (Prionace glauca). | Lenzi, J., Jiménez, S. and Domingo, A. |
| SCRS/2011/096 | Estructura poblacional de Lamna nasus (Bonnaterre, 1788) en el Atlántico sudoccidental. | Forselledo, R., Bessonart, M. and Domingo, A. |
| SCRS/2011/097 | Abundancia relativa y estructura poblacional de 6 especies de tiburones capturados por la flota uruguaya de palangre pelágico en aguas uruguayas entre 19982009. | Mas, F., Domingo, A. and Defeo, O. |
| SCRS/2011/098 | Captura de tiburones por la flota de palangre pelágico en aguas uruguayas entre 1998-2009: diversidad y CPUE. | Mas, F., Domingo, A. and Defeo, O. |
| SCRS/2011/099 | Habitat use and movements patterns of oceanic whitetip, bigeye thresher and dusky sharks based on archival satellite tags. | Carlson, J.K. and Gulak, S.J.B. |
| SCRS/2011/100 | Diel vertical movements of a scalloped hammerhead, Sphyrna lewini, in the northern Gulf of Mexico based on high-rate archival pop-off tag data. | Hoffmayer E.R., Franks, J.S. and Driggers III, W.B. |
| SCRS/2011/101 | Habitat, seasonal movements and environmental preferences of dusky sharks, Carcharhinus obscurus, in the northern Gulf of Mexico. | Hoffmayer E.R., Franks J.S. and Driggers III W.B. |
| SCRS/2011/102 | Habitat use patterns and environmental preferences of juvenile silky sharks, Carcharhinus falciformis, in the northern Gulf of Mexico. | Hoffmayer E.R., Franks J.S. and Driggers III W.B. |
| SCRS/2011/103 | Sharks caught by the Brazilian tuna longline fleet: A review. | Frédou, F.L., Tolotti, M., Frédou, T., Carvalho, F., Hazin, H., Burgess, G., Coelho, R., Waters, J., Travassos, P. and Hazin, F. |
| SCRS/2011/104 | Albacore catch rate variations in the Greek drifting longline fisheries. | Tserpes, G. and Peristeraki, P. |
| SCRS/2011/105 | A harvest control rule for depleted stocks robust to uncertainty in biological reference points. | Cass-Calay, S.L., Walter, J.F. and Brown, C.A. |
| SCRS/2011/106 | Derivation of the delta-lognormal variance estimator and recommendation for approximating variances for two-stage CPUE standardization models. | Walters, J. and Ortiz, M. |
| SCRS/2011/107 | Factors affecting Mediterranean albacore (Thunnus alalunga, Bonnaterre, 1788) catch rates from the Turkish gillnet fleet. 2010-2011. | Ceyhan, T., Akyol, O. and Ortiz de Urbina, J.M. |
| SCRS/2011/108 | Moon phase's influence on CPUE of Turkish albacore gillnet fishery. | Okan, A and Ceyhan T. |
| SCRS/2011/109 | Standardized CPUE for South Atlantic albacore by the Japanese longline fishery based on lognormal and negative binominal models. | Matsumoto, T. and Uosaki, K. |
| SCRS/2011/110 | A Generic Operating Model to evaluate the implications of population structure in tuna stocks: A bluefin tuna example. | Kell, L.T., Fromentin, JM., Bonhommeau, ,S. and Mosqueira, I. |
| SCRS/2011/111 | The Robin Hood Approach, Helping the Poor at the Expense of the Rich: An Example Based on Albacore. | Kell, L. and Pallarés, P. |
|  | Application of a Bayesian Surplus Production Model to preliminary data for South Atlantic and Mediterranean albacore. | Babcock, E.A. |

| SCRS/2011/113 | Length and sex composition of albacore, Thunnus alalunga, in the southwestern Atlantic. | Pons, M. and Domingo, A. |
| :---: | :---: | :---: |
| SCRS/2011/114 | Catch rates standardization of albacore tuna, Thunnus alalunga, caught by Uruguayan longline fleet (19832010). | Pons, M., Ortiz, M. and Domingo, A. |
| SCRS/2011/115 | A preliminary investigation of the albacore tuna (Thunnus alalunga) stock in the southern Atlantic Ocean using a non-equilibrium production model, including comparison with an age-structured production model. | de Bruyn, P., Arrizabalaga H. and Kell, L. |
| SCRS/2011/116 | Standardized CPUE of albacore (Thunnus alalunga, Bonnaterre, 1788) caught by the Spanish surface longline in the western Mediterranean. 2004-2010. | Ortiz de Urbina, J.M., Macías, D., de la Serna, J. M., Báez, J.C., García, S, Gómez-Vives, M. and Saber, S. |
| SCRS/2011/117 | An approximation to albacore (Thunnus alalunga, Bonnaterre, 1788) maturity ogive in the Mediterranean Sea by means of length- converted catch curve analysis. | Ortiz de Urbina, J.M., Macías, D., Kell, L., Arrizabalaga, H. and Saber, S. |
| SCRS/2011/118 | Conversion on sampled-CAS into CAA of South Atlantic Taiwanese albacore catch, dating from 1981 to 2010, using knife cutting algorithm. | Chang, F.C., Kao, W.Y. and Yeh, S.Y. |
| SCRS/2011/119 | Standardized CPUE of South Atlantic albacore (Thunnus alalunga) based on Taiwanese longline catch and effort statistics dating from 1967 to 2010. | Chang, F.C. and Yeh, S.Y. |
| SCRS/2011/120 | Standardized southern albacore mean annual size, from fisheries size samples 1956-201. | Ortiz, M. and Palma, C. |
| SCRS/2011/121 | Standardization of the catch per unit effort for albacore (Thunnus alalunga) for the South African tuna-pole (baitboat) fleet for the time series 19992010. | Kerwath, S.E., Winker, H. and West, W. |
| SCRS/2011/122 | Blackfin tuna (Thunnus atlanticus) in the Venezuelan fisheries. | Arocha, F., Barrios, A., Marcano, J. and Gutierrez, X. |
| SCRS/2011/124 | Le programme national d'observateurs sur les thoniers senneurs tropicaux français dans l'Océan Atlantique. | Chavance, P., Damiano, A., Cauquil, P. and Relot, A. |
| SCRS/2011/125 | Standardized catch rates of albacore (Thunnus alalunga) caught by the Brazilian fleet (1978-2010). | Andrade, H.A. |
| SCRS/2011/126 | An assessment of Mediterranean albacore based on changes in mean size. | Kell, L. |
| SCRS/2011/127 | Attempt to modify creating procedure of catch-at-size of yellowfin caught by Japanese longline tuna fishery in the Atlantic Ocean. | Ijima, H., Satoh, K., Okamoto, H. |
| SCRS/2011/128 | Japanese longline CPUE for yellowfin tuna (Thunnus albacares) in the Atlantic Ocean using GLM up to 2010. | Satoh, K., Okamoto, H., Ijima, H. |
| SCRS/2011/129 | Standardized abundance index of yellowfin tuna by the Taiwanese longline fleet in the Atlantic Ocean for 1968-2009. | Hus, C.C. |
| SCRS/2011/130 | Estadísticas españolas de la pesquería atunera tropical en el océano Atlántico hasta 2010. | Delgado de Molina, A., Ariz, J., Santana, J.C. y Sabaté, I. |

| SCRS/2011/131 | Datos estadísticos de la pesquería de túnidos de las Islas Canarias durante el periodo 1975 a 2010. | Delgado de Molia, A., Delgado de Molina, R., Santana, J.C. y Ariz. J. |
| :---: | :---: | :---: |
| SCRS/2011/132 | Estimation of the length weight relationship for bluefin tuna (Thunnus thynnus) caught by the Moroccan Atlantic traps. | Abid, N, Benchoucha,S., Lamtai, A. and El Fanichi, C. |
| SCRS/2011/133 | Small tunas caught in Moroccan Atlantic waters: Preliminary analysis. | Abid, N. |
| SCRS/2011/134 | Stomach contents analysis of swordfish (Xiphias gladius) caught off southern Brazil: A Bayesian analysis | Gorni, G.R., Loibel, S., Goitein, R., and Amorim, A.F. |
| SCRS/2011/135 | Stomach contents analysis of shortfin mako (Isurus oxyrinchus) caught off southern Brazil: a Bayesian analysis. | Gorni, G.R., Loibel, S., Goitein, R., and Amorim, A.F. |
| SCRS/2011/136 | Statistics of the French purse seine fleet targeting tropical tunas in the Atlantic Ocean (1991-2010). | Floch, L., Chassot, E., Damiano, A., Kouassi, Y., Pianet, R. and Chavance, P. |
| SCRS/2011/137 | Statistiques de la pêcherie thonière Européenne et assimilée dans l'océan Atlantique durant la période 1991-2010. | Pianet, R., Delgado, A., Floch, L., Ariz, A., Damiano, A., Sabate, I.,Kouassi, Y. et N'Gom Sow, F. |
| SCRS/2011/138 | Standardized catch rates for yellowfin tuna (Thunnus albacares) from the U.S. pelagic longline fishery based upon vessel logbook data (1990-2010). | Walter, J.F. |
| SCRS/2011/139 | Standardized catch rates for yellowfin tuna (Thunnus albacares) from the U.S. recreational fishery in the western North Atlantic Ocean, 1986-2010. | Cass-Calay, S.L., Walter, J.F. and Brown, C.A. |

# WORK PLANS OF THE SPECIES GROUPS FOR 2012 

Tropical Tunas Work Plan
No stock assessment(s) are planned for yellowfin tuna, bigeye tuna or skipjack tuna in 2012. Nonetheless, scientists are encouraged to update the fishery indicators for all three stocks in 2012. The Working Group on Tropical Tunas considered that an inter-sessional meeting is necessary to:

1. To revise biological parameters for the three species. National scientist should continue to carry out studies on biological parameters for tropical tunas. Some estimates on reproduction, maturity, lengthweight relationships, growth and other biological parameters are based on studies carried out many years ago. Changes might have occurred in the population during this period that should be considered. Furthermore, new information from other oceans should also be taken in consideration.
2. Evaluation of alternative methods for estimation of catch at age inferred from catch at size need to be conducted.
3. Problems were identified concerning standardized CPUE series for some fleets, which results in uncertainties in the assessment. Stock assessments rely heavily upon CPUE data, and, their representativeness as indices of abundance is of concern. Therefore, it is recommended to:
a) Explore methods to combine the data from different fisheries in a single longline index.
b) Explore methods to improve and combine the indices provided from different fisheries in a single combined index.
4. Stock assessments lack information on abundance of recruits and juveniles. Therefore, it is important to find alternative indices of abundance. Obtaining a better understanding of the factors that affect CPUE in purse seine (FADs, echo-sounders, satellites, etc.) and baitboat fisheries (FADs, schools associated with BB ) and subsequent development of standardized abundance indices could result in improvements of the use of these data in stock assessments.
5. It was noted that ISSF will hold a workshop on this very topic in March 2012. The Committee expressed support for the workshop and encourages ICCAT scientists to participate since it will contribute to the goals of the inter-sessional meeting.
6. It is noted that the Methods Working Group is looking at methods to develop procedures for select indices that are suitable for each assessment method. It is of interest of the Tropical Working Group to participate in their work.
7. The Working Group encourages the continuation of the cooperation with Ghana scientists. A proposal of collaboration between Ghanaian and IRD scientists is presented in the Addendum to the Tropical Tunas Work Plan.

In addition, the Tropical Tunas Working Group strongly endorses the implementation of a large-scale tagging program in 2012 and beyond (see Addendum 2 to Appendix 5 to the 2010 SCRS Report). In preparation for this program, the Working Group will develop contacts with the industry to test the feasibility of different tagging protocols for tropical tunas.

## Addendum to Tropical Tunas Work Plan

## Collaboration IRD/Ghana

ICCAT Working Group on Ghanaian tuna statistics held in Madrid (Phase II, May 30 to June 3, 2011), revised historic Ghanaian Tasks I and II, proposed some corrections and elaborated some technical recommendations to improve future data collection such as greater collaboration between Ghanaian, Ivoirian and EU sampling teams due to the frequent Ghanaian landings in Abidjan. The persons in charge of tuna statistics in these CPC had a brief meeting with the ICCAT Secretary on September 28, 2011 and identified the following actions to be held in the near future:

## Port and observer sampling

Objective: Insure that all vessels from any flag landing in each country being sampled according to established and common procedures agreed by ICCAT.

- Insure training of Ghanaian sampling teams in the field and vessels and verify correct collection and management of data
- Adopt measures allowing any vessels landing in either country to be sampled by national sampling team
- Identify and adopt data exchange protocols for logbook, sampling data and carrying capacity data collection
- Analyze the species composition from scientific sampling and from canneries

## Data management

Objective: Insure that the Ghanaian team has at their disposal and handles the same tools for data entry, management and processing used by the European and associated tropical surface fleets.

- Update AVDTH English version used by Ghana and train the local team using it
- Translate and improve data validation software (Akado)
- Translate and adapt processing software ( $\mathrm{T} 3+$ ) for Ghanaian statistics case taking into account mix fisheries (i.e., purse seiners cooperating with baitboats and large purse seiners operating alone)
- Transfer and eventually adapt software ObServe for introduction and management of observer data

## Coordination and data processing

Objective: Insure a good coordination between technical and scientific teams. Insure adequacy and evolution of procedures and tools. Enhance common analysis and scientific contributions to ICCAT Working Group.

- Participation of Ghana to the annual coordination meeting of EU and associated scientific teams monitoring tuna surface fisheries. During these annual meeting organized alternatively in France and Spain, sampling collection activities, database and tools are regularly discussed and revised and common scientific contributions to the ICCAT Working Group are identified and planned.

## The project should consider:

- Equipment (Computers, ichtyometers, etc.)
- Software development (Akado; T3 and ObServe)
- Travel funds:
a) IRD team in Ghana (1 week/yr)
b) Participation of Ghanaian team in Europe for annual coordination meetings (1 week/yr)
c) Participation of Ghanaian team to the Observer Program inter RFMOs meeting which will take place in France in April 2012 (probably associated with (b)).

## Work Plan for North and South Atlantic and Mediterranean Albacore

The Albacore Species Group does not envisage a stock assessment in 2012. Moreover, it reiterates the fact that several key uncertainties remain and significantly affect our understanding of albacore dynamics and stock status. Thus, the working group plans to focus on improving statistics as well as conducting biological research and modeling during 2012.

## North Atlantic Stock Proposed Work Plan for 2012

Given the uncertainties identified by the group, and considering the abnormal situation in the north east Atlantic fisheries during the last three years, the Group reiterates the need to carry out a comprehensive research program (Ortíz de Zárate, 2011) that had been presented for support by the Contracting Parties and allocation of funds. The main research objectives identified by the Albacore Species Group are:

1. Improved knowledge of the population dynamics of albacore in the North Atlantic.
2. Improved understanding of the interactions between the biological and ecological processes of the albacore stock and the fisheries.
3. Reduced uncertainty in stock assessment, e.g. modeling of biological processes and indices of abundance, considering spatial, environmental, behavioural and targeting issues.
4. The provision of robust management strategies for the sustainable exploitation of the stock at MSY that take into account social and economic objectives.

The Committee endorses the proposed research plan in SCRS/2010/155 and the Addendum to the Albacore Work Plan and recommends funding be initiated in 2012 or as soon as possible.

## South Atlantic Stock Proposed Work Plan for 2012

During 2012, the group will focus effort on:

- Updating time series of standardized CPUE for the main surface and longline fleets
- Exploring the influence of spatial and environmental variables on CPUE standardization
- Research on biological parameters (e.g. reproduction)

## Mediterranean Albacore Stock Proposed Work Plan for 2012

During 2012, the group will try to improve the "data poor" situation of this stock by focussing on the following tasks:

- Revision and completion Task 1 and Task II series
- Update and, where ever possible, extend back in time the existing CPUE series, so that long enough, consistent CPUE series become available for the group.
- Considering that biological data have likely been collected in different data collection programs (e.g. EU/DCR), it is recommended that a concerted effort be made to consolidate these data in an appropriate form for analyses.
- Pursue biological studies (e.g. integrated growth analysis)

## Addendum to Albacore Work Plan

## North Atlantic Albacore ICCAT Research Program

The Albacore species Group reiterates the last year proposal to initiate a coordinated, comprehensive research program on North Atlantic albacore to advance knowledge of this stock and provide more accurate scientific advice to the Commission.

The research plan will be focussed on three main research areas: biology and ecology, fisheries data and management advice during four-year period. Each of these main topics includes more detailed research aims as is presented in Ortíz de Zárate, 2011. The requested funds to develop this research plan have been estimated in a cost of 4.3 million Euros. The research program will be an opportunity to join efforts from European scientists from research institutes involved in the albacore fisheries as well as CPC's scientists involved in the research of longline fisheries of North Atlantic albacore.

| Research aim | Feasibility | Priority |
| :---: | :---: | :---: |
| 1. Biology and Ecology | 1 to 4 | 1 to 3 |
| - Reproductive biology (maturity, spawning area and season, and sex-ratio) | 2 | 1 |
| - Growth (validation, growth modelling by sex) | 1 | 1 |
| - Stock structure, genetics | 1 | 1 |
| - Natural mortality, conventional tagging (*) | 4 | 3 |
| - Habitat and migration (wintering and feeding areas; horizontal and vertical distribution), electronic tags (*) | 2 | 1 |
| - Feeding ecology (isotopes) | 1 | 3 |
| 2. Fishery data |  |  |
| - Recovery of catch, effort and size from logbooks and increase the number of size samples for longline and surface fleets | 1 | 1 |
| - Efficiency of fleets | 1 | 1 |

| 3. Modelling |  |  |
| :--- | :--- | :--- |
| - Environmental influence on the population dynamics | 2 | 1 |
| - Improve relative abundance indices by means of CPUE's analyses | 2 | 1 |
| - Improve conversion of catch-at-size into catch-at-age | 2 | 1 |
| - evaluate uncertainties under alternative hypothesis and models used | 1 | 1 |
| - Evaluate robustness of alternative management strategies, uncertainties | 1 | 1 |

Cost estimates in Euros ( ${ }^{*}$ ) all tagging activities: conventional and electronic
Biology and ecology: estimated budget €3,790,000
Fishery data: estimated budget €250,000
Modelling: estimated budget €300,000
Total estimated cost for a 4 year program €4,340,000

## Bluefin Tuna Work Plan

## 1. Overview

The last bluefin tuna stock assessment (East and West) was conducted in 2010 and the next has been scheduled by the Commission for 2012. This short intermission has not allowed time for key research projects to be completed; therefore the Group plans to focus on updating the analyses used to provide management advice in 2010. Seven days in early September are deemed to be sufficient to conduct this work and write the report.

The Bluefin Species Group reiterates that a three to four year period between assessments would be more appropriate because bluefin tuna is a long-lived species and it takes several years to detect changes in bluefin biomass in response to changes in exploitation or management. A longer period would also allow scientists more time for inter-sessional work focusing on the research activities outlined within the Bluefin Research Plan, such as large-scale tagging, aerial surveys, otolith micro-constituent analyses, genetics and reproductive biology. Moreover, such an interim would provide an opportunity for the Bluefin Tuna Species Group to improve models for evaluating bluefin dynamics and status (which can hardly be done during a stock assessment year), including forecasting and operating models that incorporate spatial variability and mixing.

The group recommends an inter-sessional meeting in 2013 to incorporate new data and biological information that have been collected during the recent national research programs and GBYP and to review progress in modeling approaches, including mixing.

## 2. Data submission

Task I and II data for the eastern and western stock through 2011 should be submitted to the Secretariat by the June $30^{\text {rd }}$ (before the July 31 deadline) so that the Secretariat can incorporate the statistics into the database. Action National Scientists and Contracting Parties.

The standardized CPUE series used in the 2010 assessment (East and West) should be updated including 2011 and made available as working papers by the first day of the meeting. The length database of ICCAT should be also checked and validated. Action National Scientists and Secretariat.

## 3. Catch and VMS summaries

The Secretariat should prepare summaries of the available catch data, catch-at-size, catch-at-age and VMS data (i.e. effort by gear/year/month/area) by the start of the meeting. Action Secretariat.

## 4. Assessment

The stock assessment work should focus on updating the analyses conducted in 2010 that were used to provide management advice. Mainline advice should be based on results from validated and documented software retained in the ICCAT catalog. These catalog entries need to be completed by April 2012. Action National Scientists.

## Billfish Work Plan

## Background

The Working Group initially proposed to conduct a Data Preparatory Meeting in 2009 and the next assessment of blue marlin and white marlin in 2010. These meetings were later postponed to 2010 and 2011 to better accommodate the 2009 Atlantic sailfish stock assessment. Due to genetic analyses and model projections results reported by Beerkircher et al. (2009), historical catches of white marlin may also inadvertently reflect significant numbers of roundscale spearfish and even longbill spearfish. For this reason, the working group felt that a white marlin assessment would not be possible in 2011, until this problem is resolved.

In 2009 the Working Group proposed to conduct the assessment through a three stage process:

1. Hold a data preparatory meeting for blue marlin in the first half of 2010 to produce catch estimates, update biological parameters, and estimate relative abundance indices for blue marlin which was successfully completed.
2. Conduct an assessment of blue marlin in 2011 and develop white marlin catch estimates, including a major effort to separate catches of roundscale spearfish (and other spearfish) from white marlin catches to the extent possible. We anticipate this effort will require an investment of funds by ICCAT through the Enhanced Research Program for Billfish (ERPBF) to accelerate the genetic analyses currently being conducted on this topic. Update biological parameters and estimate relative indices of abundance for white marlin if possible. Data in support of the blue marlin assessment and white marlin data preparatory meeting evaluation must be available at least two weeks in advance (Task I and Task II, including any revisions to historical time series, through 2009, submission of more recent data is also encouraged, but not required) of the assessment meeting.
3. Conduct an assessment of white marlin in 2012.

The last stock assessment for blue marlin was conducted in 2011 and for white marlin in 2006. No assessments have ever been conducted on spearfishes (Tetrapturus spp.). During 2009 the Working Group conducted the first successful assessments for western and eastern Atlantic sailfish stocks.

## Proposed work for 2012

## Blue marlin

All countries catching blue marlin (directed and by-catch) should contrast their information with the blue marlin catalog for Task I and II detailed in the 2010 Report of the Blue Marlin Data Preparatory Meeting (Anon. 2011d), and provide the updated information by next SCRS meeting.

The new catch estimates of blue marlin from FAD fisheries of Martinique and Guadalupe (EU France) used in the recent blue marlin assessment need to be documented and presented as an SCRS document in the next species group meeting, in order to incorporate them into the Task I database.

The group will explore the development of the historical Japanese longline fine-scale catch rate index.
Continue the Atlantic-wide study on age and growth of blue marlin.

## White marlin

Data in support of the white marlin assessment meeting must be available at least two weeks in advance (Task I and Task II, including any revisions to historical time series, through 2010, submission of more recent data is also encouraged, but not required) of the assessment meeting.

During the white marlin data preparatory meeting, it was concluded that the amount of variability in the observed ratios between white marlin and round scale spearfish (annual and inter-annual) and the insufficient spatial sampling coverage would preclude the ability to reliably estimate proportions of roundscale spearfish from white marlin catches at present. It was decided to base the white marlin assessment (2012) on the information being reporting as white marlin.

All countries catching white marlin (directed and by-catch) should contrast their information with the white marlin catalog for Task I and II given in the Detailed Report of the Blue Marlin Stock Assessment Session and White Marlin Data Preparatory Meeting, and provide the updated information at least two months prior to the white marlin assessment.

Prior to the stock assessment, CPCs should provide historical series of numbers of white marlin discarded dead and released alive so that the effect of discarding and releasing can be fully integrated in the stock assessment. Efforts should be made to obtain reliable estimates of discards with regard to quantity and length composition.

In addition to the surplus production model to be used in the assessment, the application of statistically integrated assessment models should be explored to take into consideration, seasonal catch, effort, size information for all gears, and alternative geographic stratification. Review of input parameters required for the statistically integrated model will be conducted via web-based.

During the 2012 white marlin assessment the group will explore the use of informative priors of the stock recruitment steepness parameters.

Update biological parameters for white marlin (sex ratio at size, age and growth).

## All Istiophorid species

Continue to support the improvement of biological sampling of all billfish species.
Continue to support on the age and growth of sailfish and longbill spearfish.
Continue to support on sailfish reproduction off the West Africa and Atlantic coast of South America.

## Swordfish Work Plan

## Background

The last assessments for North and South Atlantic swordfish were conducted in 2009. The next assessment is proposed for 2013

For the Mediterranean stock, the last assessment was conducted in 2010 (Anon. 2011f). The next assessment should take place not before 2013 except if negative indicators arise from the fisheries.

## Proposed work

## North Atlantic and South Atlantic

The Species Group, with the assistance of the Secretariat, should complete its work evaluating possible limit reference points for North Atlantic swordfish, as requested by the Commission in Rec. 10-02.

A list of recommended work has been provided in the Report of the 2009 ICCAT Atlantic Swordfish Stock Assessment Session (Anon. 2010c). Among those recommendations, the following were identified as high priority areas where continued efforts are required:

- Data Preparatory and Methods Meetings. Due to time constraints, recent sessions of the Swordfish Working Group have provided assessments that have updated past results using methods and approaches available at the time. The Group recognizes that newer stock assessment approaches are now available which more fully incorporate biological data and provide more complete representations of uncertainties in stock status. To allow the Group time to explore the new approaches and to assemble the data in advance of the stock assessment session, it is recommended that a working session of five days duration be convened prior to the next assessment. Based on experience with other stocks, it is recommended that the data preparatory and methods meeting take place in the same year that the assessment meeting is scheduled (2013).
- Catch. All countries catching swordfish (directed or by-catch) should report catch, catch-at-size (by sex) and effort statistics by a small an area as possible, and by month. These data must be reported by the ICCAT deadlines, even when no analytical stock assessment is scheduled. Historical data should also be provided.
- CPUE series. It is recommended that given the similarity between part of the Brazilian and Uruguayan swordfish fishing fleets and taking into account that the CPUE standardization studies of both fleets submitted at the meeting differ in their methods and results it would be desirable that scientists from Brazil and Uruguay hold inter-sessional meetings to deal with the standardization of CPUE series and processing of data from their respective fleets.
- Assignment of ages. The computer codes used for ageing swordfish in the Atlantic should be updated. The new sex-specific growth curves (Arocha et al. 2003) should be incorporated, and its impact in terms of the catch-at-age estimation, as well as its consistency with the tagging data should be evaluated before a new set of growth curves is formally adopted by the Group.
- Discards. Information on the number of undersized fish caught, and the numbers discarded dead and released alive should be reported so that the effect of discarding and releasing can be fully included in the stock assessment. Observer sampling should be sufficient to quantify discarding in all months and areas in both the swordfish directed fisheries and the tuna fisheries that take swordfish as by-catch. Studies should be conducted to improve estimation of discards and to identify methods that would reduce discard mortality of swordfish. Studies should also be conducted to estimate the subsequent mortality of swordfish discarded alive; these are particularly important given the level of discarding due to the minimum size regulatory recommendation.
- Target species. All fleets should record detailed information on log records to quantify which species or species group is being targeted. Compilation of detailed gear characteristics and fishing strategy information (including time of set) are very strongly recommended in order to improve CPUE standardization. The recommendations made by the 2002 meeting of the Working Group on Methods for looking at diagnostics in this context should be followed. The Group recommended the investigation of alternative forms of analyses in the south that deal with both the by-catch and target patterns, such as ageand spatially-structured models.
- Recruitment indices. The Group's ability to forecast stock status within the VPA is contingent on the availability of reliable indices of abundance at the youngest ages. For example, age- 1 indices of abundance are only available up to 2001. Countries that have traditionally provided such indices should update their time series, as a matter of high priority. This research should be supported at the Contracting Party level.

## Mediterranean

- Catch and effort. All countries catching swordfish (directed or by-catch) should report catch, catch-at-size (by sex) and effort statistics by as small an area as possible (5-degree rectangles for longline, and 1degree rectangles for other gears), and by month. It is recommended that at least the order of magnitude of unreported catches and discards be estimated. The Group noted that it is important to collect size data together with the catch and effort data to provide meaningful CPUEs by age.
- Gear selectivity studies. Although some work has been already done, further research on gear design and use is encouraged in order to minimize catch of age-0 swordfish and increase yield and spawning biomass per recruit from this fishery.
- Stock mixing and management boundaries. Considering differences in the catch and CPUE patterns between different Mediterranean fisheries, further research, including tagging investigations, in defining temporal variations in the spatial distribution pattern of the stock will help to improve stock assessment and management.

## Small Tunas Work Plan for 2012-2013

The following recommendations should be taken into account for improving Task I and Task II data and conducting future assessment in order to provide ICCAT with appropriate management advice for fisheries targeting small tuna:

1. All countries should report Task I and Task II data and make effort to improve knowledge on the biology and the stock structure and other relevant aspects of these species;
2. National scientists should review their catches and try to classify them by species;
3. Support national scientists working on small tuna species to participate in the ICCAT meetings;
4. CPCs should ensure a large distribution of the ICCAT small tunas species identification sheets to improve their Task I statistics data;
5. Set up an ICCAT Year Research Programme for small tuna species, the details of this program are attached as the Addendum to the Small Tunas Work Plan;
6. Continue studies on stock structure and species distribution;
7. Develop simple indicators of stock sustainability such as proportion of juveniles within the catch and statistical trends in historical catches;
8. Collaborate, as much as possible through joint Working Groups, with RFOs (GFCM, CRFM, COPACE, and CECAF) to improve and exchange basic fisheries data on SMT; Include blackfin tuna (Thunnus atlanticus) in the small tunas chapter of the ICCAT Manual;
9. Follow progress of blackfin tuna aquaculture experiments being performed by the University of Miami (United States).

Addendum to Small Tunas Work Plan

## A Proposal to Set Up an ICCAT Year Research Programme or Small Tunas (SMTYP)

## Overview

The status of small tuna stocks in the ICCAT Convention area is generally unknown. Nevertheless these species have a high socio-economic relevance for a considerable number of local communities at the regional level, which depend on landings of these species for their livelihoods.

Fisheries statistics and biological data which can provide a basis for assessing these resources and thus providing the Commission with the appropriate scientific advice for their sustainable exploitation are generally unavailable for these species.

To deal with this issue and to achieve the objectives established by the 2008 joint ICCAT GFCM working group, it is now high time to establish an ICCAT Year Research Programme for Small Tunas (SMTYP), whose the main objective for the first two years will be the collection of statistics and biological data as well as the recovery of all the historical available data in the main fishing areas, with a focus on the priority species identified by the ICCAT/GFCM in 2008. This program has a wide geographical sampling coverage to include also the Caribbean Sea.

The work plan for this programme would be as follow:
January 2012- June 2013: Priority for the collection of all the available data (statistical and biological data) in the main fishing area:

- Mediterranean and Black Sea: Bullet tuna, Atlantic bonito, little tunny and plain bonito;
- West Africa: Atlantic bonito, little tunny, bullet tuna and West African Spanish mackerel; frigate tuna, wahoo
- Caribbean area: Blackfin tuna and serra Spanish mackerel, king mackerel

July 2013: A small tuna data preparatory meeting to gather and analyze the recovered data in the main area mentioned above. Exchange of information and data between national responsible scientists in each area by email, after an agreement between ICCAT and other RFOs concerned (GFCM, CECAF, CRFM, and WECAF).

September -October 2013: Presentation of the preliminary results obtained to the SCRS Species Group.

Estimation of the preliminary budget:

| Sampling area | Participating countries | Species sampled | Total budget (Euros) |
| :--- | :--- | :--- | :---: |
| East Mediterranean | Turkey <br> Egypt | Bullet tuna, Atlantic <br> bonito, little tunny and <br> plain bonito; | $15,000.00$ |
| Central Mediterranean | Tunisia <br> Italy | Bullet tuna, Atlantic <br> bonito, little tunny and <br> plain bonito; | $15,000.00$ |
| West Mediterranean | Morocco <br> Spain | Bullet tuna, Atlantic <br> bonito, little tunny and <br> plain bonito | $15,000.00$ |
| West Africa | Morocco <br> Mauritania <br> Senegal <br> Cape Verde <br> Côte d'Ivoire | Atlantic bonito, little <br> tunny, bullet tuna and <br> West African Spanish <br> mackerel; frigate tuna, <br> wahoo | $35,000.00$ |
| Caribbean area <br> (western Atlantic) | CARICOM countries <br> Brazil <br> Venezuela | Blackfin tuna and Serra <br> Spanish mackerel | $15,000.00$ |
| Total |  |  | $95,000.00$ |

## Sharks Work Plan

## General comments

As on other occasions, the Group noted the absence of scientists from the Parties that catch shark species, thereby limiting the possibilities of access to information. This situation is not unique to this Group and this poses a problem that should be resolved by a strong commitment of the Parties.

## Work Plan

- Carry out the Ecological Risk Assessment (ERA)

Two coordinators were selected (E. Cortés and A. Domingo) to compile the necessary information provided by the national scientists to develop the ERA. The information required, which is given in detail in the report of the inter-sessional meeting (Item 3 and Appendix 4), should be available prior to the end of 2011.

## - Assessment of Isurus oxyrinchus

Contact the national scientists who could assist in running the models. Request the CPCs to conduct a review of their historical catches and carry out the following tasks two months prior to the assessment:

- Catches (Secretariat)
a) Comparison of shark catches available in the ICCAT databases compared to the Eurostat data.
b) Estimation of catch series using the tuna:sharks ratios.
c) Estimation of catch series using shark fin trade information.
- Effort (Secretariat)

Updating of the time series of estimated longline effort (EFFDIS) prior to the assessment

- Specific gear/fleet selectivities (U.S. scientists)

Estimation of the gear/fleet selectivities to use in those models that do not estimate them internally, revising the methodology and the biological data used.

- Biological data (Uruguayan scientists)

Review of the biological data on shortfin mako used in the last assessment and update them if necessary.

- Catch rates (U.S. scientists)

Compile the catch series sent by the national scientists and estimate the combined CPUE series.

## Working Group on Methods Work Plan

The plan for 2012 includes:

1. The Blue Marlin and Shark Working Groups requested the Working Group on Stock Assessment Methods to investigate and test the GLMtree model for CPUE standardization and especially for use for by-catch species.
2. Generic methods for combining and standardizing multiple CPUE series for inclusion in stock assessment models will be investigated and generic methods for these procedures will be developed.
3. Methods for selecting appropriate CPUE series for inclusion in assessment models are crucial. For many species groups there has been concern as to which CPUE series have been included in the assessments in 2011. The Group aims to develop generic protocols for the inclusion or use of CPUE series in assessment models (rigorous assessment of CPUE series including hind casting).
4. As requested by the Sub-Committee on Statistics, methods for monitoring and evaluating recreational fisheries will be investigated.
5. The Group aims to generate simulated data sets for testing generic assessment techniques and methods (multiple sets for multiple species life histories).

# ICCAT ATLANTIC-WIDE RESEARCH PROGRAMME FOR BLUEFIN TUNA (GBYP) ACTIVITY REPORT FOR 2011 (PHASE 2) 

## 1. Introduction

The Atlantic-wide Research Programme for Bluefin Tuna was officially adopted by SCRS and the ICCAT Commission in 2008, and it started officially at the end of 2009, with the objective to:
a) Improve basic data collection, including fishery independent data;
b) Improve understanding of key biological and ecological processes;
c) Improve assessment models and provision of scientific advice on stock status.

The total budget of the programme was estimated at about 19 million Euros in six years, with the engagement of the European Community and some other Contracting Parties to contribute to this programme in 2009 and in the following years. The initial year had a budget of 750,000 Euros, while the second phase had a total budget of 2.502.000 Euros (against the original figure of 3,476,075 Euros)

Phase 1 and Phase 2 activities were jointly committed by the European Community (80\%), Canada, Croatia, Japan, Libya, Morocco, Norway, Turkey, United States of America, Chinese Taipei and the ICCAT Secretariat. Some private entities provided funds or in kind support; the detailed list is available on http://www.iccat.int/GBYP/en/Budget.htm.

## 2. Coordination activities

The GBYP Phase 2 officially started on 22 December 2010, with the signature of the agreement between the European Community and the ICCAT Secretariat. A detailed weekly work-plan for 2011 was set up in the very first period of this second Phase. The GBYP Coordination staff was reinforced with a Coordinator Assistant. Dr. M'Hamed Idrissi, who started his duties on 1 March 2011. The ICCAT Secretariat nominated Dr. Laurence Kell as internal focal point for the GBYP activities.

A relevant activity at the early beginning of Phase 2 was the organisation of the three meetings planned in February, which required considerable effort. The participation of 44 scientists from 11 countries and the extremely positive comments received compensated all efforts and confirmed the positive reaction of the scientific community and stakeholders to the GBYP activities. Another meeting (the Symposium on Traps) was organised in Tangier in May 2011, with the participation of 58 scientists.

During this Phase 2 it was necessary to issue nine Calls for Tenders on various items and a total of 18 contracts were signed by the ICCAT Secretariat. The EC Grant Agreement includes 19 deliverables (periodic reports) and many have been already delivered. The administrative and desk work behind these duties was quite important. In Phase 2 of GBYP, the coordination staff participated officially in 14 meetings in various countries. Furthermore, the GBYP coordination is providing scientific support to all the national initiatives which are potentially able to increase the effectiveness of the GBYP and its objectives.

The detailed report is available in document SCRS/2011/166.

## 3. Steering Committee

The GBYP Steering Committee was renewed after the 2010 ICCAT Commission meeting. The members are the Chair of SCRS, Dr. Josu Santiago, the BFT-W Rapporteur, Dr. Clay Porch, the BFT-E Rapporteur, Dr. JeanMarc Fromentin, the ICCAT Executive Secretary, Mr. Driss Meski, and an external expert, Dr. Tom Polacheck, who was duly contracted.

The activity of the Steering Committee included continuous and constant e-mail contacts with the GBYP coordination, which provided the necessary information. The Steering Committee held two meetings (February 17, 2010; June 27-July 1, 2011), discussing various aspects of the programme, providing guidance and opinions. A third meeting is planned during the SCRS Species Group meeting, to define the activities and the budget options for Phase 3.

## 4. Data mining and data recovery

The data mining and data recovery activity continued following the objectives recommended by the Steering Committee, with a particular focus on tuna trap data series. Two Calls for Tenders were issued and seven contracts were awarded. A very important amount of data, previously not included in the ICCAT database, was recovered, particularly for tuna trap series, which now start from 1525, including about 25 million new entries for tuna trap catches and about 33,000 new entries for other fisheries. With these data, GBYP is filling many of the existing gaps, but not all, extending the historical data series back in centuries. All data were provided on the forms provided by the ICCAT Secretariat, according to the needs of the ICCAT database.

GBYP also acquired SST data for the three months of the main spawning period (May-June-July) for the years 2000-2011. These data are used for the spatial analysis of the aerial survey data and they are also available for further analyses by SCRS. Following the same approach agreed in Phase 1, aerial survey data have been analised also within the data recovery budget and the final results will be available at the end of 2011. In Phase 2, the team elaborating on the data has been requested to provide extensive survey scenarios for setting up the GBYP working programme for 2012 and the following years.

## 5. Aerial surveys

The aerial surveys have the scope to provide fishery-independent indices on various fractions of the stock. The aerial surveys targeting spawning aggregations can potentially provide trends and indices for the spawning stock biomass, while aerial surveys targeting aggregations of juveniles can potentially provide indices for recruitment. Surveys shall be conducted with a statistically sound design and for several years in order to get reliable indices. Since the beginning of the GBYP, it was decided to concentrate all efforts on spawning aggregations, while the surveys on juveniles should be conducted by the various countries concerned.

In Phase 2, as planned, the activity was preceded by a Workshop on Aerial Survey (February 14-16, 2011). The Workshop discussed how improving the methodology and which technical requirements should be necessary. The Steering Committee endorsed most of the recommendations.

A training course for pilots, professional observers and scientific observers concerned with the GBYP Aerial Survey activity was organised at the ICCAT Secretariat on May 17-18, 2011.

### 5.1 Aerial survey design

The preliminary work was devoted to updating the identification of the most relevant areas and this was carried out at the ICCAT Secretariat using the 2008 to 2010 VMS data from tuna purse seine vessels. It was agreed to concentrate efforts only on areas where the PS fishing activity was more intense in these last three years and 4 or 5 sub-areas were identified, under two different scenarios.

The study for the aerial survey design was committed to the same team who provided the design for Phase 1, adopting the same methodological approach (DISTANCE software). The design was provided on March 30, 2010 and the ICCAT Secretariat provided the revised file to submit the survey data.

### 5.2Aerial survey on spawning aggregations

The aerial survey on spawning aggregations was carried out by three companies, selected over four tenders and the contracts were discussed and agreed on May 17, 2011. All tenders were able to get the flight permits from Spain, Italy, and Malta in due time, but it was not possible to get flight permits from Syria, while the permit from Turkey was released after the expiry date of the survey. All these problems imposed a revision of one contract and, at the same time, a revision of the aerial survey design, limiting the areas to three (Balearic area, South Tyrrhenian Sea and central Mediterranean), in agreement with the Steering Committee. The aerial survey started at the beginning of May and was completed on July 15, 2011.

The monitoring of the sea surface temperatures and sea state and winds was carried out by the coordination team and data were provided to the various teams in real time. The wind in the western Mediterranean and in the Tyrrhenian Sea, some international constrains in the central Mediterranean, and some technical problems of two aircraft created additional operational problems for the aerial survey in Phase 2. Three aircraft and teams conducted the surveys in the various sub-areas, while a fourth aircraft and its team was stopped in Turkey. The aerial survey data have been provided on schedule by all teams and the individual reports are already available.

A contract was provided to the same team that provided the data elaboration in Phase 1, to analyse the aerial survey data. The interim report was provided in due time (September 19, 2011) and the results are considered very useful for improving and developing the aerial survey activities in the following years, also providing the various scenarios for a comprehensive Mediterranean survey in Phase 3, as requested by the Steering Committee. This second year activity of aerial surveys confirmed the validity of the methodological approach in general, as one of the very few able to provide fishery independent data and trends. At the same time, the problems encountered showed the need to get very precise commitments from the CPCs concerned, in order to carry out the necessary flight permits on time.

The final report concerning the elaboration on aerial survey data, the spatial analyses and the complete range of scenarios and designs for the comprehensive surveys will be provided before the end of Phase 2, according to the contract.

## 6. Tagging

The GBYP tagging activity was planned from Phase 2. The tagging design, elaborated as a draft in Phase 2, was better defined in the first part of Phase 2. The operational meeting on biological sampling was held at the ICCAT Secretariat in Madrid on February 17, 2011, to discuss the many aspects of this complex activity and the GBYP Tagging Design, including the GBYP Tagging Manual, which were officially adopted. The meeting was attended by 42 scientists.

The Tagging Design was officially adopted by the Steering Committee and it is considered extremely relevant, because an appropriate tagging activity is a better estimate of natural mortality rates (M) by age or age-groups and/or total mortality ( Z ), of course if the tag reporting rate substantially improves, reaching a sufficient level by major fisheries and areas, and this should improve knowledge on the habitat utilisation and movement patters of bluefin tuna in the various areas. It is the base for carrying out the tagging activities in the following years, with important implications on the GBYP budget.

A sufficient number of conventional tags were acquired on time (10,000 single barb dart, 8.000 double barb small darts and 2,000 double barb big darts), along with a sufficient number of tag applicators and 50 PIT readers.

### 6.1 Tagging activity

The GBYP tagging activity was defined by the Steering Committee on February 17, 2011 and refined during the summer meeting (June 27-July 1, 2011). A Call for Tenders was issued on May 12, 2011 and only one bid was received. The bid was not awarded and another Call for Tenders was issued on June 11, 2011. Another bid was submitted and awarded on July 9, while the contract was released on July 29, 2011 to a Spanish consortium of six entities.

The tagging activity will be carried out on juvenile bluefin tunas (age 0 to age 3) in the Bay of Biscay by baitboats (about 1250 tunas), in the area of Gibraltar by baitboats (about 1250 tunas), in the western Mediterranean by a purse seiners (about 1250 tunas) and in the central Mediterranean by a purse seiners (about 1250 tunas). A complementary tagging activity will be carried out, on an opportunistic basis, by the sport fishermen (possibly 500-700 tunas).

The tagging activity started immediately, and several operational problems were encountered, mostly due to bad weather conditions, but the first mid-term report, submitted by September 23, 2011, shows that about 2,000 tunas have been tagged to date and that the tagging activity will continue until the end of the period.

Another tagging activity, not included in Phase 2 due to budgetary problems, was carried out with electronic tags in a Moroccan trap, thanks to the cooperation of several institutions, the tuna industry and WWFMEDProgramme (the details are included in the detailed report). A total of 11 large tunas were tagged and several tags are providing surprising and extremely interesting data.

### 6.2 Tag awareness campaign

According to the recommendations provided by the Steering Committee in all meetings, the GBYP started a tag awareness campaign, for the purpose of improving the tag recovery and reporting rates. This activity, which was carried out by ICCAT and SCRS for all species since various years, needed to be strengthened and further
improved, particularly after the start of the massive tagging activities by the GBYP. For this reason, it was decided to find a specific slogan, a dedicated logo, two types of posters and a leaflet, to be translated in Arabic, English, French, Greek, Japanese, Italian, Portuguese, Spanish and Turkish, and distributed capillary in the entire ICCAT Convention area for the purpose of reaching all stakeholders in all fisheries. A Call for Tenders was issued on July 28, 2011, and three bids were received. One bid was partially awarded and the first report was submitted on September 23, 2011 and the drafts of the various designs are now available. The final version will be available soon for printing the material before completing the tagging campaign. The tagging awareness campaign is coupled by a tag rewarding campaign strongly recommended by the Steering Committee. It was decided to improve the ICCAT annual lottery with GBYP rewards for tags recovered from bluefin tuna and regularly reported to ICCAT. High level rewards will be given for the recovery of each electronic tag from bluefin (1000 Euros) or for additional prizes for the annual ICCAT tagging lottery (an annual prize of 1000 Euros for the first tag drawn and two prizes of 500 Euros each, respectively for the second and third tags drawn, to be delivered during the ICCAT Tag Lottery. Within the same item, the ICCAT Secretariat and the GBYP coordination are working to detect an attractive design for the T -shirts to be used as rewards for each conventional tag recovered. It is also considered very important to provide immediate feedback to the tagging teams and the tag recovery person, informing both of them about the history of each tag.

## 7. Biological and genetic sampling and analyses

Biological and genetic sampling and analyses have been planned from Phase 2 . The details were discussed during a specific operational meeting held at the ICCAT Secretariat on February 17, 2011, which was attended by 42 scientists. The meeting discussed in depth all the various aspects and suggested having a common scheme. The Steering Committee, on the same day, endorsed this suggestion and recommended issuing a Call for Tenders for a "Biological Sampling Scheme" to be used to more precisely establish the sampling levels in the various areas and fisheries in the Phase 2 activity. The Call was issued on March 11, 2011, and only one bid was received, which was awarded to a consortium of 13 institutions from 8 countries on July 14, 2011.

Taking into account that some areas and fisheries included in the "Biological Sampling Scheme" cannot be sampled due to concurrent geo-political factors, the sampling activity under contract includes now a total of 1950 samples, including 50 larvae, 1300 for genetic tissue, otoliths and spines, and 600 for genetic tissue, otoliths, spines and gonads. A first report was received on September 24, 2011 and about 1000 tunas have been sampled as of that date, while the analytical works had already started.

The GBYP activity will be supported by a twin programme carried out by NOAA-NMFS, which will focus the research activities on the western Atlantic Ocean.

## 8. Modelling approaches

To ensure that modelling work would be started this year, the GBYP issued a Call for Tenders on March 15, 2011 for Stock Assessment Modelling, for a first set of contracts. These were: (a) one contract for a risk analysis to identify the main perceived sources of uncertainty related to assessment and advice, and (b) two contracts to help develop new assessment and advice based on various data sets being collected and the new knowledge being gained under the GBYP. Unfortunately, only one bid was received for the second theme. Two contracts were awarded on April 5, 2011 and the methodologies were presented at the ICCAT Working Group on Stock Assessment Methods (WGSAM) on June 27-July 1, 2011, where one day (June 28) was devoted to bluefin tuna issues. The preliminary reports on the work done were presented at the Bluefin Tuna Species Group on September 29, 2011. Additional work was developed by a team of SCRS scientists together with Dr. Laurie kell of the ICCAT Secretariat and presented at the WGSAM.

## 9. Cooperation with ROP

The GBYP coordination, together with the ICCAT Secretariat, is maintaining the contacts between the two consortiums in charge of the biological sampling and tagging and the ROP observers, for strengthening the cooperation and providing opportunities.

## 10. Definition of GBYP publication policy, editorial and data rules

The GBYP publication policy, along with editorial and data use rules adopted in Phase 1 were updated by the GBYP Steering Committee during the last meeting (June 26-July 1, 2011). They are available on the ICCAT web site at: http://www.iccat.int/GBYP/en/PubRules.htm

## 11. GBYP web page

The ICCAT-GBYP web page, which was created in the last part of Phase 1 , is usually regularly updated with all documents produced by GBYP; in some cases, due to the huge workload, some sets of documents are posted all together. The updating also includes the budget page, where all contributions (monetary of in kind) are regularly listed, to ensure full transparency.

## 12. Following activities

The next phases of the Atlantic-Wide Research Programme for Bluefin Tuna will mostly include activities able to provide fishery independent data and indices within the time-frame of the whole programme and in agreement with the GBYP general plan adopted by the SCRS and the ICCAT Commission. Additional activities will be developed for the modelling approaches.

The Steering Committee and the GBYP Coordination agreed to continue the discussion during the SCRS meeting, where the various options will be discussed and selected, with the necessary budget variations. It is to be noted that the current budget figure is very far from the budget figure adopted by the Commission in 2009 for Phase 3, which was on the order of about 6.3 million Euros and this is caused by the announcement of the reduced contribution available from some CPCs.

GBYP Phase 3 (still temporarily under the reduced minimum budget perspective) will include, in principle, the following activities:

## 1) Coordination.

2) Data mining, data retrieval and data elaboration, including data input in the ICCAT database.
3) Aerial surveys, including the updating of the aerial survey design and the third year survey on spawning aggregations. Based in the results of the analyses of the 2010 and 2011 aerial surveys data, the Steering Committee recommended, and the SCRS approved, the extension of the survey area in 2012 and forward as the only way to obtain reliable independent indices of spawners from aerial surveys to be used for monitoring the stock. This extension will imply additional costs on the order of 1.2-255 million Euros per year ${ }^{1}$ for more than one year (up to and including 2022 considering $\mathrm{CV}=0.4$ ); the figure in the budget includes the minimum amount for conducting an extended survey and the additional activities required by the Steering Committee). Without the adequate financial support and the guarantee of flight permits these surveys would not secure obtaining reliable results.
4) Tagging, including conventional tagging, a limited electronic tagging ( 50 tags) and activities to improve tag reporting, with the related rewards; a recapture campaign was also requested by the Steering Committee and approved by the SCRS;
5) Biological sampling, including hard parts sampling for ageing and micro-constituent analysis, genetic sampling and related analysis.
6) Modelling, including two workshops, risk analysis, alternative MF and modelling trials.

The GBYP Phase 3 budget and activities will be revised by the Steering Committee and the SCRS in the last part of Phase 2, according to the updated budget perspectives and the research needs. The provisional calendar for the meetings in Phase 3 will be defined after these decisions.

[^12]Table 1. GBYP reduced minimum budget for Phase 2 (2010-2011) and Phase 3 (2011-2012).

| GBYP PHASE 2 (2010-2011) |  | GBYP PHASE 3 (2011-2012) |  |
| :--- | ---: | :--- | ---: |
| Allocation | Amount ( $($ ) | Allocation | Amount ( () |
| Coordination | 453,00000 | Coordination | $463,980.00$ |
| Data mining, data recovery, data <br> elaboration, Trap Symposium | $149,000.00$ | Data mining, data recovery, data <br> input and processing | $133,000.00$ |
| Aerial survey (including updating <br> design, workshop and training <br> course) | $465,000.00$ | Aerial survey (including updating <br> design and the workshop) | $1,370,000.00$ |
| Tagging (conventional, PITs, tag <br> recovery and reporting, rewards) | $890,000.00$ | Tagging (conventional, PATs, tag <br> recovery campaign and reporting, <br> rewards) and an operational meeting | $1,776,000.00$ |
| Biological sampling (including hard <br> parts, genetic sampling and analysis) | $505,000.00$ | Biological sampling (including hard <br> parts, genetic sampling and analysis) <br> and an operational meeting | $540,000.00$ |

## ICCAT ENHANCED RESEARCH PROGRAM FOR BILLFISH

(Expenditures/Contributions 2011 \& Program Plan for 2012)

## Summary and Program objectives

The ICCAT Enhanced Research Program for Billfish, which began in 1987, continued in 2011. The Secretariat coordinates the transfer of funds and the distribution of tags, information, and data. The General Coordinator of the Program is Dr. David Die (USA); the East Atlantic coordinator was Mr. Paul Bannerman (Ghana), while the West Atlantic Coordinator is Dr. Eric Prince (USA).

The original plan for the ICCAT Enhanced Research Program for Billfish (ICCAT, 1987) included the following specific objectives: (1) to provide more detailed catch and effort statistics, particularly for size frequency data; (2) to initiate the ICCAT tagging program for billfish; and (3) to assist in collecting data for age and growth studies. During past Billfish Species Group meetings, the Billfish Species Group requested that the IERPBF expands its objectives to evaluate habitat use of adult billfish, study billfish spawning patterns and billfish population genetics. The Billfish Species Group believes that these studies are essential to improve billfish assessments. Efforts to meet these goals continued during 2011 and are highlighted below.

The program depends on financial contributions, including in-kind support, to reach its objectives. This support is especially critical because the largest portion of billfish catches are coming, in recent years, from countries that depend on the support of the program to collect fishery data and biological samples. In recent years most of the financial support came from ICCAT funds but in 2009 and 2010 there were also contributions from Chinese Taipei.

## 2011 Activities

The following is a summary of the activities of the Program; more details of activities conducted in the western Atlantic can be found in SCRS/2011/163. Ten observer trips onboard Venezuelan longline vessels were completed by July 2011 and some more may be completed before the end of the year. Sampling of Venezuelan artisanal catches also continued in the central coast of Venezuela. Biological sampling from both the pelagic longline and artisanal Venezuelan fisheries has continued collecting biological samples of sailfish for reproductive studies, and for white marlin and spearfish for genetic identification. This year this program recovered 7 tagged billfish by July 2011.

The IERPB continued to support Brazil in their collaboration with United States institutions for testing the performance of circle hooks on board commercial vessels, deploying pop-up satellite tags, tissue sampling for genetic identification of white marlin and spearfish, and fin spine sampling for age and growth studies. With IERPB support, Uruguay continued to collect samples this year for age, growth and genetic identification of billfish onboard longline vessels.

In West Africa the program continued to support a review of billfish statistics in Ghana, Senegal and Cote d'Ivoire. Improvements of catch records from these countries are reflected in the Task I tables for billfish, and were obvious during the blue marlin assessment and white marlin data preparatory meeting of 2011. Support of this program facilitated the estimation of relative abundance indices for blue marlin from Ghana, and studies of blue marlin spawning off Côte d'Ivoire. The program also profited from the cooperation with Spanish scientists that collected genetic samples of billfish on-board longline vessels for the study on white marlin and spearfish identifications and of U.S. scientists involved in the processing of genetic samples.

Documents that were produced in 2011 with the benefit of direct support of the IERPB were SCI/2011/021, SCI/2011/026, SCI/2011/033, SCRS/2011/034, SCRS/2011/049, SCRS/2011/050 and SCRS/2011/163.

## 2012 Plan and activities

The highest priorities for 2012 are to support the collection and preparation of data relevant to the upcoming white marlin stock assessment. Such priorities will require to:

- support the monitoring of the Uruguayan, Venezuelan and Brazilian longline fleets through onboard observers, reporting of conventional tags, and biological sampling,
- support the monitoring of the Venezuelan artisanal fleet,
- support the collection of biological samples in West Africa,
- support the collecting and processing of samples of billfish for genetic studies, and
- support the monitoring billfish catches from west African fishing fleets.

All these activities depend on successful coordination, sufficient financial resources and adequate in-kind support. Details of IERPB funded activities for 2012 are provided below. Some of these will complement general improvements in data collection made with the support of the ICCAT data improvement program.

## Shore-based sampling

Sampling of artisanal and small scale fisheries to support the estimation of catch and effort statistics will be focused on fleets contributing the largest parts of the catch and/or those having traditionally provided the higher quality data in the past, to ensure the preservation of an uninterrupted time series of catch and relative abundance indices.

## West Atlantic

Sampling at landing sites will be conducted for gillnet landings in central Venezuela.

## Eastern Atlantic

Monitoring and sample collection will be supported for the artisanal fisheries of Ghana, Sao Tome, Côte d'Ivoire, and Senegal.

## At-sea sampling

## West Atlantic

Continued support will be provided to the sampling made onboard the Uruguayan, Venezuelan, and Brazilian vessels that have been supported in the past by IERPB.

## Tagging

The program will need to continue to support the conventional tagging and recapture reporting conducted by program partners.

## Biological studies

The biological sampling program for collecting and processing genetic samples from billfish, particularly white marlin and spearfish, will continue in 2012. This program will aim to determine the ocean-wide ratio of white marlin to roundscale spearfish, including how this ratio has changed through time. The later will be done by taking advantage of the spine collections (from Venezuela, Uruguay, Brazil, Spain, and the United States) collected in the past with the support of the IERPB. Additionally the program will this year fund and provide sample kits for additional collection of samples for genetic identification of white marlin and spearfish. These sample kits and corresponding instructions will be distributed to scientists that can facilitate collection of genetic samples of white marlin and spearfish.

Efforts to collect biological samples for reproduction, age and growth studies requires IERPB support to facilitate cooperation from fleets that are monitored with IERPB funds. The emphasis of biological sampling for age, growth, and reproductive studies will be directed at sailfish and longbill spearfish.

## Coordination

## Training and sample collection

Program coordinators need to travel to locations not directly accessible to promote IERPB and its data requirements. This includes travel to West African countries, as well as the Caribbean and South America by the
general coordinator and the coordinator from the west. Strong coordination and between activities of the IERPB and the ICCAT data fund and financial support from the data fund will continue to be required.

## Program management

Management of the IERPB budget is assumed by the program coordinators, with the support of the Secretariat. Reporting to the SCRSC is responsibility of the coordinators. Countries that are allocated budget lines for program activities need to contact the respective program coordinators for approval of expenditures before the work is carried out. Invoices and brief reports on activities conducted need to be sent to the program coordinators and ICCAT to obtain reimbursement. These funding requests need to be done according to the ICCAT protocol for the use of funds from ICCAT (2011 Report of the Sub-Committee on Statistics (see Appendix 7).

## 2011 Budget and Expenditures

This section presents a summary of the contributions and expenditures for the ICCAT Enhanced Research Program for Billfish during 2011. The 2011 budget recommended by the Billfish Working Group for IERPB was $€ 46,850.00$. The contributions made to the IERPB for the 2011 program were an allocation of $€ 30,600.00$ from the regular ICCAT budget and a contribution of $€ 8,000$ from Chinese Taipei. Carryover funds remaining from previous year were $€ 7,259.30$ thus total funds available for 2011 were $€ 45,859.30$ (Table 1). As a consequence most planned activities of the program will be able to be carried out. Expenditures to date in 2011 have been $€ 17,011.00$ but an additional $€ 27,700.00$ are already committed to other activities that have either taken place in 2011 or will take place between October and December. The estimated balance of the program at the end of 2011 will be €1,148.30€ (Table 2).

In-kind contributions to the program continued to be made during 2011. INIA and the University of Oriente (Venezuela), Universidad Federal Rural de Pernambuco (Brazil), and Instituto Dirección Nacional de Recursos Acuáticos (Uruguay) have provided personnel time and other resources as in-kind contributions to the at-sea biological sampling program, thereby reducing the amount of funds needed for this activity from the ICCAT billfish funds. The Instituto Español de Oceanografia (Spain) contributed by paying for the costs of collecting and shipping biological billfish samples for genetic analyses collected on board Spanish vessels. The U.S. National Marine Fisheries Service funded a part of the cost of processing genetic samples for identification of white marlin and spearfish. Travel costs and personnel time of the program coordinators were absorbed by the U.S. National Marine Fisheries Service, the University of Miami, the Ghana department of fisheries and by the ICCAT Data fund.

## 2012 Budget and requested contributions

The summary of the 2012 proposed budget, totaling $€ 45,850.00$ is attached as Table 3. The Working Group requests that the Commission maintain its contribution of $€ 30,600.00$ for 2012 but that it increases to $€ 35,000$ for 2013 to cover increasing needs of the IERPB program (see Table 4). The requested contributions from ICCAT are necessary to fully implement the IERPB 2012 and 2013 program plans. During 2012 the Program will continue to require contributions of $€ 14,100$ from other sources, such as those so generously provided recently by Chinese Taipei, to achieve all its objectives.

The consequence of the Program failing to obtain the requested budget will be to stop or reduce program activities for 2012 including: (1) important at-sea observer trips in Venezuela, Uruguay and Brazil; (2) coordination travel for eastern coordinators; (3) sampling of artisanal fleets in the western and eastern Atlantic (4) sampling and processing of genetic, age and growth samples; (6) promotion of conventional tagging activities, including distribution of tag recovery incentives. All these activities are critical to continue the improvement of the information available to the SCRS for the assessment of billfish.

## Conclusion

The IERPB has been credited for major improvements in the data supporting the last ICCAT billfish assessments. The Program needs to continue to facilitate the collection of biological and fishery information. The IERPB Program will continue to require support from ICCAT and other sources to operate and to address the needs of the Commission, specially the upcoming assessment meeting for white marlin. Although considerable benefits will accrue from various outputs of the ICCAT data improvement program, the IERPB is the only program that exclusively focuses on billfish. By having this focus it is in the best position to ensure that the
research and monitoring activities not covered by the ICCAT data improvement program are given some minimal resources. The IERPB is an important mechanism towards completing the goal of having the highest quality information to assess billfish stocks.

Table 1. Summary budget for 2011 for the Billfish Program.

| Source | Euros ( $€$ ) |
| :--- | ---: |
| Budget recommended by the Working Group | $46,850.00$ |
| Balance at start of Fiscal Year 2011 | $7,259.30$ |
| Income (ICCAT Regular Budget and others) | $38,600.00$ |
| Expenditures and obligations (for details see Table 2) | $-44,711.00$ |
| Estimated Balance | $\mathbf{1 , 1 4 8 . 3 0}$ |

Table 2. Detailed 2011 Budget \& Expenditures (as of October 1, 2011).

|  | Euros ( $€$ ) |
| :---: | :---: |
| Balance transferred from 2010 | 7,259.30 |
| Income Total | 38,600.00 |
| ICCAT Commission | 30,600.00 |
| Chinese Taipei | 8,000.00 |
| Available funds | 45,859.30 |
| Expenditures | -17,011.00 |
| Venezuela | -11,000.00 |
| Ghana | 3,000.00 |
| Senegal | 3,000.00 |
| Bank charges | -11.00 |
| Balance (as of October 1, 2011) | 28,848.30 |
| Funds obligated until end of 2011 | -27,700.00 |
| Uruguay | -2,000.00 |
| Brazil | -5,000.00 |
| São Tomé | -2,000.00 |
| Côte d'Ivoire | -3,000.00 |
| Tag rewards | -500.00 |
| Genetic samples | -15,000.00 |
| Bank charges | -200.00 |
| Total estimated expenditures | -44,711.00 |
| Estimated balance December 31, 2011 | 1,148.30 |

Table 3. Summary budget of the ICCAT Enhanced Research Program for Billfish for 2012.

| Source | Euros ( $€$ ) |
| :--- | ---: |
| Balance at start of Fiscal Year 2012 (estimated) | $1,148.30$ |
| Income (Requested from ICCAT Regular Budget) | $30,600.00$ |
| Other contributions) | $13,100.00$ |
| Expenditures (see Table 4) | $44,800.00$ |
| BALANCE | $\mathbf{4 8 . 3 0}$ |

Table 4. Detail of expenditures planned for 2012.

| Source | Amount |
| :--- | ---: |
| STATISTICS \& SAMPLING |  |
| West Atlantic shore-based sampling: |  |
| Venezuela | $5,000.00$ |
| West Atlantic at-sea sampling: | $6,000.00$ |
| Venezuela | $2,000.00$ |
| Uruguay | $5,000.00$ |
| Brazil | $3,000.00$ |
| East Atlantic shore-based sampling: | $3,000.00$ |
| Senegal | $3,000.00$ |
| Ghana | $2,000.00$ |
| Côte d’Ivoire | $10,000.00$ |
| Sao Tome | $5,000.00$ |
| Processing of Genetic samples * | 500.00 |
| Collection of genetic samples * |  |
| Lottery rewards - tagging billfish | 100.00 |
| COORDINATION | 200.00 |

TOTAL ..... 44,800.00

Authorization of all these expenditures depends, on sufficient funds being available by ICCAT and from other contributions.

* Number of samples collected and processed will depend on the final budget of the Program.

# REPORT OF THE MEETING OF THE SUB-COMMITTEE ON STATISTICS 

(Madrid, Spain, September 26-27, 2011)

## 1. Opening, adoption of Agenda and meeting arrangements

The Sub-Committee on Statistics met at the ICCAT Secretariat (Madrid, Spain) on September 26-27, 2011. The meeting was chaired by Dr. Gerald Scott and Dr. Guillermo Diaz served as rapporteur. The Agenda was accepted and adopted by the Sub-Committee (Addendum 1 to Appendix 7).

## 2. Review of fisheries and biological data submitted during 2011

The Secretariat presented information held in the "Secretariat Report on Statistics and Coordination of Research in 2011" related to fisheries and biological data submitted in 2010, including revisions to historical data.

### 2.1 Task I (nominal catches and fleet characteristics)

Based on the percentage of CPCs that reported data on landings and those that reported data by the deadline, the Sub-Committee recognized that improvements in data reporting had occurred during the past few years. The Sub-Committee therefore requested the Secretariat to prepare some statistics demonstrating the observed improvement in data reporting. The Secretariat also noted an improvement in the reporting of fleet characteristics since 2005. Once again, the Sub-Committee acknowledged the improvement in reporting these data that has traditionally been overlooked by many CPCs and requested the Secretariat to explore the possibility of requesting CPCs the submission of historical fleet characteristic data.

As in previous years, the Sub-Committee once again discussed how to differentiate between non-reporting (no compliance) or the lack of reporting due to no catches. The Sub-Committee discussed the possibility of preparing electronic forms with a default value of 'zero landings' for all species or another suitable alternative, so CPCs only would have to update those species for which they have landings. Although this was viewed as a potential solution, there was some concern about the impact that such approach would have on the ICCAT databases by incorporating very large amounts of observations for 'zero catches'.

The Sub-Committee discussed extensively the deadlines of data reporting requirement. It was noted that the table prepared by the Secretariat that indicated compliance with data submission requirements did not take into consideration the specification of the data needs provided in the species work plans. Therefore, the SubCommittee requested the Secretariat to review the table based on that information. Furthermore, the SubCommittee discussed that tables showing compliance with data submission deadlines should only used the July 31 deadline. The Secretariat requested that the species work plans be specific enough with respect to data requests so to facilitate the work of the Secretariat.

The Sub-Committee also noted that although Ghana has reported data prior to the meeting on "Review of Ghanaian Statistics", the Secretariat's table showed that there were some concerns with Ghana's data submission. The Secretariat indicated that Ghana did not use the approved electronic forms for the submission of its data.

The Sub-Committee discussed that reviewing compliance with data submission requirements had resulted in drifting the role of the Sub-Committee from a scientific endeavour toward a role more related to a compliance committee. There was a general agreement that the Sub-Committee should be more involved on reviewing the submitted data for its scientific value for stock assessment purposes instead of only focusing on submission deadlines. The Sub-Committee generally agreed on the need to develop a system to better characterize the quality of the submitted data beyond if they were submitted by the deadline or not and recommended that future work of the Sub-Committee be oriented more toward data quality evaluations.

### 2.2 Task II (catch \& effort and size samples)

Like with Task I data, the Sub-Committee acknowledged the improvements observed in the reporting of Task II data. However, the Secretariat noted that there are still cases when the Catch and Effort data are reported without
reporting effort or with unconventional effort units (e.g., longline effort expressed as number of fishing days). The Secretariat indicated that in these cases the data are still useful because they can be included in the CatDis estimation. However, the Secretariat indicated that in these cases it still follows up with these CPCs to attempt to obtain the correct information.

### 2.3 Tagging

After the presentation of the received tagging information, the Secretariat clarified that the Moroccan bluefin tuna tagging information was included in the EU Spain data as part of a collaborative project. Uruguay asked the Secretariat about reporting additional tagging information beyond the point of release and recapture such as more detailed information collected by the electronic tags and also maps. Canada informed the Sub-Committee that they have additional tagging information for 2010-2011 that still has to be reported. Similarly, Brazil indicated that it is preparing a comprehensive report with Brazilian tagging activities.

### 2.4 Trade information

The Secretariat summarized the available Trade-based information in the "Secretariat Report on Statistics and Coordination of Research in 2011". The Sub-Committee discussed that at present, these data are most applicable for compliance related issues, but that historically, at least for some species, data similar to these have been used to estimate unreported catch. Now that a wider array of species is being tracked, especially through the transhipment observer data, these data should be further evaluated for use in verifying catch reports. To do this, a fuller range of conversion factors for product to whole weight would be needed along with careful evaluation to avoid double counting of the same fish and to account for lags between time of capture and market.

### 2.5 Other relevant statistics

## Observer programs

- Discussion relevant to Rec. [10-10]

The Secretariat presented a table summarizing the information received from different CPCs on their national observer programs. Table 1 compares the reports received against the number of flag-gear combinations from which such reports might be expected under [Rec. 10-10]. At the time of the Sub-Committee meeting, only a low proportion of responses that could have been submitted have yet been received by the Secretariat. This information will be further reviewed by the 2012 SCRS in order to develop its response to the Commission as called for under [Rec. 10-10].

It was recommended that the Secretariat develop a simple form to be filled out by CPCs to better characterize and compare the different observer programs in addition to the table already developed by the Secretariat. This form should promote improved reporting by CPCs regarding the information requested under [Rec. 10-10].

The Sub-Committee interpreted [Rec. 10-10] to mean that reporting requirements of domestic observer coverage only applied to longline, purse seine, and bait boat fisheries.

The Sub-Committee requested those CPCs that have implemented or are experimenting with monitoring schemes alternative to observer programs for vessels less than 15 m (e.g., cameras, etc.) to present such information to the SCRS in 2012.

- Discussion Relevant to Rec. [10-04]

Information was received on the Moroccan observer program on the trap fishery which has $100 \%$ observer coverage. This information was referred to the Bluefin species group for preparation of a response to the Commission on this particular recommendation.

## 3. Updated report on the ICCAT relational database system

The "Secretariat Report on Statistics and Coordination of Research in 2011" provided an update on the ICCAT relational database system. The Sub-Committee acknowledged the progress made on data bases and noted the following.

## E-BFT-VMS data

The Sub-Committee indicated that VMS data from Mediterranean purse seines and other vessels fishing for bluefin tuna could be used to identify spawning grounds. However, as previously indicated by the SubCommittee, the 6 hr time interval between VMS reports does not have enough resolution to be used for more useful scientific purposes, such as evaluation of PS catch-effort patterns. The Sub-Committee recommended that VMS signals should be reported at no more than two hour interval. The Secretariat indicated that the presented data was filtered so data received from vessels docked in a port were not included. The Sub-Committee encouraged the Secretariat to use algorithms that can identify fishing activities from 'searching times'. It was also noted that the data presented by the Secretariat showed fishing activities in the Black Sea. The Secretariat clarified that these data could correspond to registered bluefin tuna vessels that were fishing for other species such as small pelagic species.

The Sub-Committee briefly discussed the value of requesting VMS data from other ICCAT fisheries and from VMS associated to FADs.

## 4. National and international statistical activities

The "Secretariat Report on Statistics and Coordination of Research in 2011" summarized the activities undertaken by the Secretariat regarding international statistical activities.

The Sub-Committee encouraged the Secretariat to continue with these efforts.

## 5. Report on data improvement activities

### 5.1 ICCAT-Japan Data and Management Improvement Project

Discussion of the JDMIP activities was deferred to Plenary.

### 5.2 Data Funds from [Res. 03-21] and other ICCAT funds

The Secretariat presented a series of proposed guidelines to standardize the use of and the process to access these funds. In general, the Sub-Committee agreed that some of the guidelines drafted by the Secretariat were not flexible enough to accommodate the needs of the SCRS. The Sub-Committee proposed that the guidelines for use and access to these funds as provided in Addendum 2 to Appendix 7, be further considered by Plenary for adoption.

### 5.3 Data recovery activities

The "Secretariat Report on Statistics and Coordination of Research in 2011" described a number of data recovery activities undertaken in this year. The Sub-Committee discussed a number of aspects of these activities, as follows.

The Sub-Committee reviewed the major finding of the intersessional meeting that reviewed the Ghanaian fishery statistics. It was recognized that some segments of the Ghanaian fleet seemed to have been underreporting their catches. The inter-sessional meeting indicated that for 2010 Ghana may have underreported a total of 20,000 t of tropical tunas, all species together. Furthermore, during the yellowfin tuna stock assessment carried out in 2011 it was concluded that the corresponding underreporting yellowfin tuna catch would have an impact on the results of the assessment which would result in a worsening of the estimated stock status. Therefore, the Sub-Committee recognized the need to solve this particular issue with respect the Ghanaian Task I reported data. The SubCommittee was also concerned about the effect of this underreporting with respect to bigeye tuna.

In the case of bluefin tuna landing updates for Turkey and Algeria, there is no documentation supporting the proposed revisions and these data have not been used in any assessments, yet. Therefore, approval of these revisions is pending upon the receipt of supporting documentation. S. Tome submitted revisions for 2005-2007 for several species. This was a reclassification of landings by species, and the amount of total remained the same. Although documentation supporting the changes has been provided by S. Tome, such document has not yet been reviewed by the SCRS. Pending this review, the Sub-Committee recommended adoption of these revisions since
they identified total landings at species level, compared to the aggregated values previously available. The SubCommittee requested the Secretariat to contact these CPC to request the missing supporting documents.
[Senegal provided new shark landings data from its artisanal fisheries. However, the Sharks Species Group has not reviewed these data or the supporting document yet. Pending that review, the Sub-Committee recommended adoption of these revisions as they are at the species level and provide much finer resolution than previously available].

## Revisions or new submission

- C\&E data

Regarding the updates to the C\&E data base, it was questioned if the different flags proposing revisions provided documentation supporting the changes to be made. The Secretariat indicated that, in some cases, the changes corresponded to data that was reported as NEI and then reclassified with a flag. This information is not new, and it has been used in past assessments as NEI (PS and BB only). In the case of Venezuela, the updated data corresponded to data that was resubmitted using the electronic forms. The changes to the Ghanaian data are pending approval by the species group, but these data were used in the most recent yellowfin stock assessment in sensitivity runs. EU-Portugal (mainland) submitted a revision of data (LL) now reported by 1 x 1 , but there is no supporting documentation yet available. The Sub-Committee recommended that this finer-scale data be admitted to the data base, pending adequate documentation. In summary, the revised data submitted by Venezuela, Trinidad Tobago, and EU-Portugal is missing the supporting documentation and, therefore, it cannot be incorporated to the ICCAT database yet, although the Sub-Committee recommended these data revisions be incorporated into the database as soon as adequate documentation is made available.

- CAS or Size data

During the Yellowfin Tuna Stock Assessment Session, Japan submitted revised CAS of YFT-LL for the period 1995-2010. Documentation supporting the review of the data was also provided during the yellowfin tuna assessment in an SCRS document. The Sub-committee inquired if the newly applied methodology could be extended to other species caught by the Japanese longline fleet and recommended that Japanese scientists consider if the methodology used for yellowfin tuna is also appropriate for other species.

### 5.4 BFT-E Observer data

These data should be reported by the company in charge of the observer program during the Bluefin Tuna Species Group meeting and as such, was not commented upon by the Sub-Committee.

### 5.5 Weekly catch reports

The Sub-Committee considered this a compliance issue, although the data may provide some basis for validation of recent year catch for use in projections.

### 5.6 Transhipment observer data

Transhipment observer data has been used in the past for bigeye tuna to identified IUU. It was noted that the data is reported using a variety of product types (fillet, etc.). The Sub-Committee indicated that there is a need to develop conversion factors and to identify method to avoid double counting the same fish. It was indicated that in the development of such conversion factors it will be necessary to take into consideration that these factors are most probably fleet specific. The Sub-Committee also requested clarification of the different product definition. It was suggested that an analysis of using transhipment data to validate landing and to identify the limitation of these approach should be conducted by the trade specialists.

The Sub-Committee was concerned regarding commenting on issues that are related more to compliance than to science being the transhipment data one of them. The Sub-Committee emphasized the need to look at these data as a scientific tool instead of using them to make compliance determinations.

## 6. Review of publications and data dissemination

The "Secretariat Report on Statistics and Coordination of Research in 2011" provided a summary of publications and data dissemination efforts over this year. The Sub-Committee acknowledged this work and approved the progress made.

### 6.1 Review of the results of the ICCAT-ALR publication agreement

The Sub-Committee recommended that the ICCAT-Aquatic Living Resources publication agreement be continued.

### 6.2 Development of shark and other species identification sheets

The Sub-Committee was informed that the shark identification sheets would be available in the coming week. The Sub-Committee applauded the progress made on this topic and remained anxious to view the final product. The Sub-Committee agreed with the recommendation from the Billfish Species Group to develop ID cards for Istiophorids.

## 7. Review of progress made for a revised ICCAT manual

The Sub-Committee supported the Secretariat's proposal to contract out the development of the LL gear chapter of the ICCAT Manual. The Sub-Committee agreed with the recommendations to update the description of white marlin and spearfishes (RSP, Tetrapturus georgei, SPF, Tetrapturus pfluegeri) and to expand the description of several shark species to the corresponding chapter.

## 8. Consideration of recommendations from 2011 inter-sessional meetings

The Recommendations from inter-sessional meetings referred to the Sub-Committee are contained in Addendum 4 to Appendix 7. Discussion points raised by the Sub-Committee are reported below.

### 8.1 Recommendations of the Working Group on the Organization of the SCRS

The Sub-Committee endorsed the recommendations of the Working Group. The Sub-Committee noted in particular, the following:

- Increase analytical and data base management support at the Secretariat.

The recommendations for increased data base, analytical, and by-catch coordination support were endorsed by the Sub-Committee and were recommended to Plenary. These positions should be included in the 2012 Budget of the Secretariat, but because the proposed budget was already circulated in July and only included the by-catch coordinator position, it presents a difficulty. The timing between preparation of the Budget and the identified needs of the SCRS needs to be better coordinated. The Sub-Committee recommended the SCRS Chair and Executive Secretary consult on procedures to avoid such difficulties.

- Quality assurance and transparency

The Sub-Committee endorsed the recommendations for use data fund to contract help to develop stock assessment documentation during meetings and to invite experts from other tRFMOs to participate in our stock assessments.

### 8.2 ICCAT-GBYP Symposium on Trap Fisheries for Bluefin Tuna

The Sub-Committee could not endorse the recommendation to keep traps open after quotas were achieved without further consideration and justification offered by the Bluefin Tuna Species Group.

### 8.3 Tropical Tuna Species Group Inter-sessional Meeting on the Ghanaian Statistics Analysis (Phase II)

The Sub-Committee endorsed the recommendations of the Ghanaian statistics working group and recommended Plenary to adopt them.

### 8.4 Atlantic Yellowfin Stock Assessment Sessions

The Sub-Committee discussed and endorsed the recommendation to use market based information to validate logbook catch reports and recommended expanding such approaches to other species, when such information is available.

### 8.5 Sharks Data Preparatory Meeting for the Application of the Ecological Risk Assessment

The Secretariat indicated that the tagging database was missing a number of shark tagging information from the United States, and they are currently working directly with scientists from this CPC to solve this issue. The SubCommittee agreed that these data should be acquired as soon as possible and inquired if the reporting of tagging data should still be done through a CPC's tagging correspondents. In response, the Secretariat indicated that there was still a list of tagging correspondents, but it should be reviewed and updated as appropriate with the help of the CPCs.

The Sub-Committee also asked for clarification with respect to the recommendation of exploring methods to estimate shark catches from purse seines fisheries. It was indicated that there are some publications that indicated the existence of shark by-catch in purse seine fisheries, and therefore the need to quantify these catches since the majority of shark catch information is only from longline fisheries. The Sub-Committee recommended that such estimates should be incorporated into the ICCAT data base as soon as possible.

### 8.6 Inter-sessional Meeting of the Sub-Committee on Ecosystems

The Sub-Committee recommended that the Sub-Committee on Ecosystems should continue to develop the protocols for collection of by-catch data.

The Secretariat asked about what species will be considered as "by-catch" for the purpose of reporting. The SubCommittee on Ecosystems pointed out the lack of consensus on a "by-catch species". The Sub-Committee on Statistics indicated that the focus should be on quantifying the total catch regardless of if a particular species is considered target catch or by-catch.

### 8.7 GBYP Steering Committee Meeting

It was indicated that in the case of bluefin tuna there is a precedent that requires a minimum of $10 \%$ sampling. It was indicated that for some large fisheries a $10 \%$ sampling effort might not be necessary and instead of quantity it is more important to obtain representative samples from the different fishery strata.

The Sub-Committee reiterated that there is a need to quantify the quality of the information reported and the quality/representativeness of size samples from different fisheries is a question that fits within this issue. It was commented that a $10 \%$ sampling could be adopted as a general rule that could be revised on a fisheries basis. It was also indicated that for the future analysis to better characterize the level of sampling that will provide information to improve management recommendations should be conducted. However, this decision still does not address the problem of assuring that the collected samples are representative.

### 8.8 2011 Blue Marlin Stock Assessment Session and White Marlin Data Preparatory Meeting

There is information available on marlin by-catch by European purse seine fisheries which could be used to validate the information that has already been reported to ICCAT. It was indicated that using observer data estimates of total marlin by-catch in this fishery have been obtained; however, the estimates have a large level of uncertainty.

The Sub-Committee also indicated that a recommendation emphasizing the need to report live releases could be included to the list of general recommendations.

## 9. Implication of data deficiencies

### 9.1 Current data catalogues of major species by stock

The Secretariat presented to the Sub-Committee the updated data catalogues (Table 2). The Sub-Committee indicated that cross checking Task I landing with size reports is a good approach to identify data deficiencies.

### 9.2 Implications of identified deficiencies in future stock assessments

The Sub-Committee agreed that these deficiencies should be discussed by each species group, particularly by those that conducted an assessment in 2011.

### 9.3 Proposals for data recovery plans and improvement on data collection systems

There was a recommendation of improving data sharing and collection from entities that collect data on Mediterranean albacore. Similarly, there was a proposal to continue with efforts to collect shark historical data.

## 10. Review of existing data submission formats and procedures

The Sub-Committee discussed the need of forms to submit seabird, sea turtle, other by-catch, and observer data. It is expected that this task will be taken by the by-catch coordinator. The Secretariat indicated that it only received observer data from one CPC. The Sub-Committee recommended that CPCs report observer data to help the Secretariat to develop electronic forms for the submission of this type of data. The Sub-Committee approved the Secretariat's recommendation of adding spearfish to the list of main ICCAT species.

## 11. Future plans and recommendations

### 11.1 Infrastructure and technology

The Group acknowledged the important improvements carried out by the Secretariat with respect to infrastructure and related support. It noted that additional improvements to the databases should be pursued.

### 11.2 Data bases

Documentation of database structures and data quality issues that are not to be addressed in 2011-2012 are a reflection of the Secretariat's increasing work load. It was suggested that if the Secretariat increases accessibility to the data bases, the species working group could do their own data extractions and therefore allowing the Secretariat to focus their effort on other areas. The Secretariat commented that increasing data accessibility and developing the corresponding documentation is a time consuming task and that the current ICCAT schedule does not permit the Secretariat to conduct this type of work. However, the Secretariat is slowly moving into that direction. The Secretariat also indicated that because the data base documentation is not completed it will be difficult for scientists that are not familiarized with the details of the data bases to extract the proper data for particular analysis. This particular situation emphasizes the recommendation of the Sub-Committee on the need to provide more support to the Secretariat in the form of more staff.

## 12. Other matters

### 12.1 Third Joint Meeting of the Tuna RFMOs (Kobe III)

The SCRS Chair presented to the Sub-Committee information on the last Kobe III meeting held in La Jolla, USA, in July of the present year. The explanation of the Chair focused on the science discussions in the meeting. The discussions focused on the review of past Kobe recommendations on science, the Joint Technical Working Group on By-catch, and specific issues to be considered by the Kobe III participants. The Technical Working Group prepared a work plan that included the harmonization of data collection among tRFMOs, identification guides, and release protocols among tRFMOs and to develop a centralized by-catch data base. The specific science issues that were discussed during the meeting included data confidentiality rules and addressing common issues in RFMO's scientific bodies. The Secretariat indicated that it has already been contacted by the Joint

Technical Working Group on By-catch to request information on the ICCAT by-catch metadata base in order to integrate it into a common system (BMIS) and it is pending SCRS approval for this activity. The Sub-Committee recommends Plenary that this activity be conducted as soon as possible.

### 12.2 Sport fishing information

The Sub-Committee inquired if the Secretariat has received any more information on sport fishing. The Secretariat indicated that some CPCs continue reporting their sport fishing catches which could be reported to the Commission. In addition, the Secretariat indicated that no new questionnaires with sport fishing information have been submitted by any CPC.

In view of this, the Sub-Committee updated a response to the Commission drafted by the 2010 Committee, but which was not taken up by the Commission's Working Group on Sport and Recreational Fishing (Addendum 4 to Appendix 7).

## 13. Adoption of the report and closure

After review by the Sub-Committee, the report was adopted and the meeting was closed on 27 September 2011. The Convener thanked all participants for their work.

Table 1. Metiers for which observer programs might be expected under the definitions of Rec. [10-10]. Green shaded cells represent metiers for which reports responsive to Rec. [10-10] have been received and reviewed at the Sub-Committee on Statistics meeting in 2011. Blank cells represent metiers for which such reports might be expected based on recent (2000s) reported catches for these flag-gear combinations indicated. Grey cells indicate flag-gear combinations for which no recent (2000s) catches have been reported and therefore such reports are not expected. This information is not necessarily applicable for compliance issues.

Table 2. SWO-N. Catalog of northern Atlantic SWO Stock available: Task I (T1, in tonnes) and Task II (T2 availability; yellow= t2-CE only; light green= t2-SZ only; dark green= T2-CE + SZ) statistics, between 1980 and 2010. For t2sz, either size frequencies and CAS were considered.

## Agenda of the Sub-Committee on Statistics

1. Opening, adoption of Agenda and meeting arrangements
2. Review of fisheries and biological data (new and historical revisions) submitted during 2011
2.1 Task I (nominal catches and fleet characteristics)
2.2 Task II (catch \& effort and size samples)
2.3 Tagging
2.4 Trade information (BFT Catch Documentation Scheme; SWO/BET Statistical Documents)
2.5 Other relevant statistics (North Atlantic detailed data including discards and effort statistics
3. Updated report on the ICCAT relational database system
4. National and international statistical activities
4.1 International and inter-agency coordination and planning (FAO, CWP, FIRMS)
4.2 National data collection systems and improvements
5. Report on data improvement activities
5.1 ICCAT/Japan Data and Management Improvement Project
5.2 Data Funds from [Res. 03-21]
5.3 Data recovery activities
5.4 BFT-E VMS data
5.5 BFT-E observer data
5.6 BFT-E weekly catch reports
5.7 Transhipment observer data
6. Review of publications and data dissemination
6.1 Review of the results of the ICCAT-Aquatic Living Resources publication agreement
6.2 Development of sharks identification species sheets
7. Review of progress made for a revised ICCAT Manual
8. Consideration of recommendations from 2011 inter-sessional meetings
9. Evaluation of data deficiencies pursuant to [Rec. 05-09]
9.1 Current data catalogues of major species by stock
9.2 Implications of identified deficiencies in future stock assessments
9.3 Proposals for data recovery plans and improvements on data collections systems
10. Review of existing data submission formats and procedures
10.1 Formats and e-FORMS improvement (to account for current fishery practices)
10.2 Improvements to the ICCAT coding system
10.3 Rules applied to historical data revisions
10.4 Rules used to determine deadlines for submitting statistics
10.5 Other related matters
11. Future plans and recommendations
12. Other matters
13. Adoption of the report and closure

## Protocols to Follow for the Use of Data Funds \& Other ICCAT Funds

## Introduction

Among the existing ICCAT funds, some like those available in the JDIMP or the EU Fund for Capacity Building, have their own user protocol defined by the Steering Committee or by the terms of reference of the corresponding contracts. In other cases, the Secretariat establishes the criteria in collaboration with the SCRS.

Considering that these funds were created to support the active participation in the work of the SCRS of scientists of countries with less resources, this document aims to define the objectives of funding and to establish protocols for more fluid and productive usage. The proposal has been developed based on the most recent recommendations and requirements of the SCRS.

The lines defined in this document and the protocols established will be applied to those funds available that do not have their own protocol.

## Use of funds

Three large groups are considered: Improvement of Statistics, Capacity Building, and Supporting Work of the SCRS

## 1. Improvement of statistics

The improvement of statistics can be considered at various levels:
1.1 Recovery of historical data. The reconstruction of historical data series is fundamental, both for the overall assessment of the resources, and for the analysis of fishery dynamics. This section would include:

- Data searches and incorporations from various sources.
- Computerization of the data (e.g., logbooks) which are available in other formats (in paper copy, etc.).
- Data analysis, including sampling systems, observer programs, etc.
1.2 Development of support material. Sampling and observer programs require additional information such as observer manuals, species identification sheets, etc. The funds could be used for the preparation and publication of this material.
1.3 Development of programs for data entry and processing. The development of data entry and processing programs is essential and the funds should finance this work.

In any of the abovementioned sections, and if so warranted, the funds can be applied to hire experts or to finance the travel expenses of the Secretariat's staff to carry out tasks to support the work teams involved. These tasks can be achieved through data analysis, support in situ for the collection of information and sampling, observers, development of support material, development of data processing programs, etc.

These funds would also be used to finance the participation of scientists from countries that do not have their own means to be able to participate in the SCRS meetings.

## Protocol for the allocation of funds

To finance the improvement of statistics the following conditions must be met:

1. There should be an explicit recommendation from the SCRS or a formal approval by the SCRS Chair on the need and/or interest of the data to be recovered, development of support material and/or development of the data processing programs, i.e. explicitly referring to the identification of the period to be recovered, the fishery, type of data, type of support material, data processing programs, etc.
2. The SCRS, through the corresponding Species Groups and the Sub-Committee on Statistics (SC-STAT), or the SCRS Chair will develop a work plan.
3. The SCRS or the SCRS Chair will define the procedure to carry out the work plan (e.g., hiring of experts, funding local teams, etc.).
4. The Secretariat will facilitate the process defined in the work plan.
5. The decision on the selection/approval of the projects and contracting experts will be made by the SCRS or the SCRS Chair. The selection of the experts will be made by the Secretariat after consulting the SCRS Chairman and, if contemplated in the defined procedure, with a Selection Committee.

The conditions for financing the participation of scientists at SCRS would be the following:

1. Pertain to developing countries that do not participate by their own means.
2. Present a request, within a deadline defined in the protocol approved by the SCRS in 2010, including a detailed description of the applicant's contribution to the meeting.
3. The Secretariat will process the request and, after obtaining agreement from the rapporteurs of the Species Groups involved and/or from the SCRS Chairman, will carry out the necessary procedures in accordance with the protocol approved by the Committee.
4. The invited scientists are expected to participate actively in the meeting and likely present scientific documents.

## 2. Capacity building

The Working Group on the Organization of the SCRS noted a decreasing trend in the participation of scientists of CPCs in the work of the SCRS and stressed the need to strengthen their active involvement in this work. One of the causes pointed out by the Group referred to the increasing complexity of the models used and the difficulty to access them. Faced with this, the Group stressed the need to establish capacity building policies which continually develops skills that will result in an overall understanding of the assessment procedures that are carried out within the SCRS.

In this sense, the third meeting of tuna RFMOs insisted on the need to coordinate efforts among the different organizations to develop a more efficient training policy.

In line with these recommendations, the funds could be used to:

### 2.1 Develop training programs structured by levels and impart training courses.

2.2 Develop supporting learning materials (manuals, applications, web pages, etc.). This section could include both the development of specific applications such as the payment of fees for the use of the material already developed, as well as potential expenses linked to a tutorial in training modules.
2.3 Exchange of scientists between research centres. In 2011, for the first time, a scientist from a developing country spent training time at the IRD-IFREMER centre in Sète.
2.4 Finance the participation at the SCRS meetings of scientists from countries which do not have their own means to support the participation of this scientist in the meetings.

The financing of participants at training courses will be limited to scientists from countries which do not have their own resources to support its participation. However, the funds can be applied towards hiring experts to give courses and/or to develop the learning material, independent of the degree of development of their country of origin.

## Protocol for the allocation of funds related to Capacity Building

1. A training course may be requested by a developing Country and/ or may be proposed by the SCRS;
2. When requested by a developing country, a work plan for the training Course should be submitted for the approval by the SCRS or by the SCRS Chair. When proposed by the SCRS, the corresponding Species Groups and/or the Sub-Committee on Statistics will develop a work plan.
3. The SCRS or the SCRS Chair with the Secretariat will define the procedures to carry out the work plan (e.g., hiring of experts, funding local teams, etc.), in coordination with the relevant developing State.
4. The Secretariat will facilitate the process defined in the work plan.
5. The decision on the selection/approval of the projects and contracting experts will be made by the SCRS Chairman, in coordination with, if contemplated in the defined procedures, a Selection Committee and in consultation with the Secretariat.

In the case of a request for a stay at research centres, the protocol shall remain the same as above; however it will include some additional conditions:

- The request, which must be presented at least two months before initiating the stay, should include:
a) A justification supporting the stay and a work plan describing the activities to be undertaken.
b) A letter of consent from the director of the center where the researcher works.
c) A letter from the director of the center accepting the scientist's stay.
d) In case a visa is required, the applicant should negotiate this directly with the country of the center where he /she will carry out the stay.
e) ICCAT will not provide any health and/or accident insurance during the stay.
- Following the stay, a document must be presented to the SCRS including a detailed description of the work carried out during the stay and the results obtained.

## 3. Support the work of the SCRS

One consequence of the decreasing participation of CPC scientists at SCRS meetings is that the Secretariat has increased its participation during the meetings of the SCRS, which went from supporting the work carried out by the SCRS scientists to, in some cases, carrying out a major part of the assessment work. This situation does not correspond with the philosophy of the work of the SCRS or with the structure and means which the Secretariat has available. This preparatory work would be particularly indicated in the application of integrated or similar statistical models which require a large volume of data. The current ICCAT funds could support the work of the SCRS in different ways:
3.1 Contracting experts to develop models, analysis, data preparatory work, and/or participate in the assessments.
3.2 Financing the participation of external experts at the SCRS meetings. In the case that the expert is associated with a tRFMO, such participation would have a double benefit of a peer review (ICCAT Performance Review recommendation) and encouraging the coordination and exchange among tuna RFMOs (Kobe III recommendation).

As in the section above, financing could be applied to any expert who meets the required conditions.

## Protocol for the allocation of funds

1. The SCRS Chair, after consultation with the appropriate subsidiary body of SCRS, should specify the profile of the experts in detail, the work to be carried out and, in some cases (e.g., for peer review) provide the Secretariat with a list of potential reviewers.
2. The SCRS Chair, after consultation with the appropriate subsidiary body of SCRS and in consultation with the Secretariat, will define the procedure to carry out the work plan (e.g., hiring of experts, funding local teams, etc.).
3. The Secretariat will facilitate the process defined by the SCRS or SCRS Chair.
4. The decision on the selection/approval of the projects and/or contracting experts will be made by the SCRS or the SCRS Chair. The contracting of the experts will be made by the Secretariat after consulting the SCRS Chairman and, if contemplated in the defined procedure, with a Selection Committee.

Addendum 3 to Appendix 7

## Recommendations from Inter-sessional Meetings Referred to the Sub-Committee on Statistics

## 2011 ICCAT South Atlantic and Mediterranean Albacore Stock Assessment Sessions

- The Group recommended continuing the work towards integrating the various growth estimate attempts for the Mediterranean albacore. If possible, by including the original datasets in the various works being published so far.
- It was recommended to further investigate on the nature and magnitude of the historical trap catches of albacore in southern Portugal, as well as implications for the assumed stock structure.
- The Group noted that information on some albacore fisheries exists (e.g. FAO, GFCM, Eurostat) which is not incorporated into the ICCAT database. Moreover, the group detected some datasets with either too small ( $<30 \mathrm{~cm}$ in 2009) or too large ( $>150 \mathrm{~cm}$ ) individuals reported, or important catches by "unclassified" gears. The group emphasizes the need for complete and accurate Task I and Task II data from the main fisheries catching albacore in the Atlantic and the Mediterranean in order to be able to give adequate management advice. Thus, it recommends that all CPCs make an effort to revise the available information and submit it to ICCAT, following the ICCAT standards, before the next assessment.

## Meeting of the Working Group on the Organization of the SCRS

## Secretariat support for SCRS

- Further additions to data management staff at the Secretariat should be made to assure that current and future demands, which are likely to increase further, for rapid processing and summarization of the needed information sets is possible. The pace of increasing demand on just the database management aspects for the Secretariat has occurred at double the rate of the addition of staffing to deal with the increased workload of the Secretariat. This is especially true since the mid-2000s with rapid increases in the amount of information the Secretariat is expected to process and rapidly summarize.
- Given the success realized following the requirement that Task I and II data be submitted in specific electronic formats, a similar requirement for compliance information should be implemented. Although compliance issues are not normally within the purview of the SCRS, it is clear that the workload associated with compliance monitoring, compounded by the fact that the vast majority of compliance documentation is submitted in paper/pdf rather than in a standard electronic format, has adversely impacted the ability of the Secretariat to fulfil SCRS data processing needs in a timely and complete manner.

## Quality assurance and transparency

- In support of further quality assurance and transparency, a checklist for stock assessment documentation should be developed and implemented to improve the current situation and allow easy location of the model inputs, software, and outputs (including the underlying data supporting tables and figures). As the complexity of stock assessment workshops has increased, the amount of documentation needed to support the management advice provided to the Commission has increased. There is wide variability in the quality and quantity of documentation, including the basic input data, models applied, and outputs from the assessments. In addition, stricter guidelines streamlining reports (both detailed and executive summaries) need to be implemented in order to improve the quality of the documentation and advice provided.
- Collaboration between tRFMOs scientific committees should be further enhanced as such collaboration provides a good basis for quality assurance through peer review and exchange of expertise and experience. In line with the outcomes of the Kobe2 (Barcelona) discussions, benefits from joint, horizontal working groups devoted to cross-cutting issues such as seabird by-catch and data standardizations issues, should be pursued.

## ICCAT-GBYP Symposium on Trap Fisheries for Bluefin Tuna

- The historical data series from the tuna trap fishery archives that have been recovered in the last two years provide an important improvement of the ICCAT data base. The Symposium recommends that further details be made available by national scientists, for a better understanding of the natural fluctuations of the stock, and to improve the standardised CPUEs taking into account the most relevant variables.
- It is also recommended that these traps be considered as "ICCAT Tuna Observatories", by increasing their full cooperation with ICCAT and its scientific programs, by providing full access to their detailed catch and effort data, by providing that biological sampling can be carried out, and by allowing the tag and release of bluefin tunas.
- For standardizing the CPUE series from trap fisheries, it is recommended that:
- Records be kept of landed fish as well as released fish from the traps.
- Records be kept of size and/or age information of the fish caught, and indices be developed by age or age groups if there are changes in the size distribution of fish caught in the traps.
- Regional-wide studies be promoted on the trends of catch rates at size-age from different tuna traps.
- The Symposium participants also recommended that these traps be kept open for a time period long enough to maintain the consistency of their long-term statistical series.

## Tropical Tuna Species Group Inter-Sessional Meeting on the Ghanaian Statistics Analysis (Phase II)

- The Group recognized the extraordinary work conducted by Ghanaian scientists with very limited resources for sampling and collection of fishery statistics corresponding to the Ghanaian fleet fishing tropical tunas. However, taking into consideration the relevance of tropical tuna catches landed in Tema by this fleet and fleets of other nationalities and the very limited material and human resources currently available, the Group remains concerned. While some positive steps have been taken Ghana to address staffing and infrastructure issues previously identified by SCRS, current levels are not yet sufficient to fully meet data collection obligations for Task I and II statistics for the overall fleet.
- The Group found that for several fleet segments, very little sample data were available and only partial or no total annual catch was available through official data collection mechanisms. The behaviour of certain segments of the fleet, which includes transfer of catch at sea to carrier vessels for landing at various ports, prevents adequate sampling of catch (by gear) and makes access to logbooks at port, difficult, if not impossible, to achieve for some fleet segments. While the Group made attempts to estimate catch and size characteristics for those fleet segments, these estimates remain highly uncertain. The Group is concerned that a fraction of the Ghanaian fleet behaves in ways that could be considered in contravention of the objectives of the ICCAT Convention. In particular, because obligatory data collection and reporting is generally not possible under the current practices, proper monitoring of the full fleet activity is not carried out.
- The Group reemphasized the SCRS view of convenience for the Ghanaian sampling program to follow, as closely as possible, the sampling scheme protocol used in the EU fishery in order to facilitate the joint analysis of standardized data. In that sense, as different teams are responsible for the Ghanaian and European purse seine sampling in Côte d'Ivoire, it would be convenient to continue enhancing collaboration and coordination between both groups.

## Improvements in data collection infrastructure and procedures to fully address data reporting obligations

- The Group recommends development of a permanent structure, adequately equipped, with the necessary human resources, in charge of collecting detailed information on the tropical tuna fisheries (Task I, Task II (C/E) and sampling of catches (Task II size, biological parameters).
- The Group recommends the Ghanaian authorities make the necessary efforts to conduct a proper monitoring of the activities of their fleet in order to guarantee the necessary coverage for the collection of statistical data required. Such monitoring should include at-sea observations, including sampling catches, as well as collection of complete and accurate fishing logbooks from the vessels.
- Furthermore, the Group recommends that data collection protocols be instituted in Ghana which in make it possible to sample catches landed, regardless of flag, as is the process used in Abidjan.

## Mechanisms for meeting data obligations

- The Group recommended that mechanisms to improve capacity for meeting data collection and reporting obligations, including industry financial contributions or inter-governmental arrangements, be instituted to enhance financial support for staffing and infrastructure improvements needed to meet the above recommendations.

## Technical recommendations

- The Group noted a difference in the percentage of skipjack sampled on Ghanaian landings by scientists and at the cannery. This divergency in species composition remains unexplained. The Group recommended that an intensive multispecies sampling scheme should be done in Tema, validating in parallel the tunas sampling and data entries done by scientists and at the cannery. This comparative sampling should be done under the responsibility of a scientist fully experienced in multispecies tuna sampling.
- The Group noted a relative lack of larger yellowfin tuna in the sample records from Ghana for a series of years. While the Group found that very large yellowfin are infrequently encountered in the Ghanaian fleet, compared to the European purse seine fleet, it was discovered during a site visit to Ghana and in subsequent discussion, that while larger fish are sampled, they are measured in a different way and recorded on separate sheets, which may not have been computerized. The Group recommended that all measures of fish should be on the same sheet, to avoid loss of these measures.
- The Group noted that there are some observer data now available and becoming available for the tropical tuna fleets for characterizing size composition and potentially species composition of the catches as well. Currently these data are not used in the processes for estimating species and size composition of the catches for the European fleet because of concerns about their potential bias. The TGG recommends that observer data be fully analyzed and compared to port sampling information to judge the adequacy of current observer sampling protocols for these purposes.
- The Group noted that the metrics used for comparing Ghanaian and European fleet performance make use of somewhat different components of the catch. For Ghanaian vessels landing in Tema, "market fish" which do not go to canneries are recorded and officially reported in Task I data. For European vessels and Ghanaian vessels landing outside of Tema, the landed fish which do not go to canneries are characterized as "faux poisson" but are not recorded or officially reported as part of Task I. While there is now ongoing sampling to estimate "faux poisson", it is not yet considered part of official Task I. The TGG recommends that official Task I statistics should include all sources of fishery induced mortality and that CPCs endeavour to achieve this recommendation.
- The Group also noted that the procedures used during the meeting for re-estimating Ghanaian species and size composition made use of both newly available observations and assumptions for time-area combinations where no direct observations were available. While the Group considered the assumptions used to be plausible and resulting in a substantial improvement in the available Task II data base, there are other assumptions that are also plausible and the Group did not have sufficient time to evaluate sensitivity of the outcomes to a range of plausible assumptions. The Group recommends that such evaluations be carried out in the future before accepting any one set of assumptions as the best available.
- The Group recommended working toward development of an improved and harmonized sampling and data processing process for the Ghanaian fleet. In this sampling scheme, it is necessary to separate free school from FAD sets in the data collection and processing. The data validation software (AKADO) needs to be English-language and the processing system made more user friendly and should be introduced into the ICCAT software catalogue as one means of validation. Furthermore, the Working Group recommended that data recovery efforts continue.
- The Group recommends that discrepancies identified between the ICCAT authorized vessel list and the results of in-field investigation of active vessels in the Ghanaian fleet be further evaluated.

## Atlantic Yellowfin Stock Assessment Sessions

- The Group recommended that historical and present samples of size frequency (in contrast to raised and substituted size-frequency) be recovered and provided to the Secretariat in support of conducting stock evaluations that make use of the sampling fraction in calculations.
- Recalling the previous SCRS recommendation, the he Group reaffirmed that catch and catch at size necessary for fine-scale scientific analysis be reported by CPCs in at most $5 \times 5$ degree resolution.
- The Group recommended that procedures for collection of size samples should be reviewed to assure that there is no size bias in sampling, as the Group suspects that such size-bias may be occurring in certain fisheries.
- The Group recommended the evaluation of market information sources or other alternative ways to improve the accuracy of catch estimates coming from logbooks.
- The Group recommended re-evaluation of the length-weight and associated relationships which were developed on historical information. It is possible that such relationships have changed as the stock condition has changed over time.

## Sharks Data Preparatory Meeting for the Application of the Ecological Risk Assessment

- Urge scientists to participate in the 2012 assessment of shortfin mako and comply with the deadlines for the submission of data and documents (see item 5).
- The Group recommended that the CPCs provide data to analyze conventional tag shedding rates.
- The information on tagging should specify the sex of sharks tagged by scientific personnel.
- Allow scientific observers to collect biological samples (vertebrae, tissues, reproductive tracts, stomachs) from species whose retention is prohibited by current regulations that are dead at haulback.
- The Group recommended that the CPCs explore methods to estimate catches of sharks in purse seine fisheries.
- The Group recommended that CPCs report shark Task II size data by sex since this information can be easily collected by observers in most cases.
- The Group suggested to incorporate the description of the 6 species of sharks that have been included in recent Recommendations (ALV, BTH, OCS, SPL, SPZ, SPM) in Chapter 2 of the ICCAT Manual in the bycatch species section.

## Recommendations Pertinent to the Sub-Committee on Statistics from the Inter-sessional Meeting of the SubCommittee on Ecosystems

- The Sub-Committee recommends that guidelines for the presentation and analysis of by-catch statistics be developed in conjunction with the Working Group of Stock Assessment Method (WGSAM) and that these guidelines be made available as part of the ICCAT Manual. Furthermore, the Sub-Committee should work with WGSAM to evaluate how these data can be used as part of a risk management advice framework.
- The Sub-Committee re-iterated the need for all CPCs to collect and provide by-catch data to the SCRS, and highlighted the need for further analysis combining species distribution and by-catch data to fill existing data gaps, and to monitor levels and impacts of by-catch.
- With regard to sea turtle by-catch mitigation, the Sub-Committee reminds the obligations of CPCs to provide the by-catch information as required in Rec. 10-09 in 2012.
- The Sub-Committee noted that the By-catch Coordinator position remains unfilled and strongly recommends that this position be recruited promptly. The Sub-Committee also recommended modifications to the job description (Section 5) to better reflect its needs at this time, and to facilitate the ability to recruit an individual with the appropriate skills.
- The Sub-Committee recommends that national scientists from CPCs provide available information which would facilitate to provide a response to the Commission regarding Resolution 05-11 (Sargassum).
- The Sub-Committee recommends that the Secretariat attempt to collate user manuals or protocols describing data collection from CPC observer programs. Also, an attempt should be made to identify historical changes to the data collection protocols that might complicate data analyses and interpretation.

## GBYP Steering Committee Meeting

- Excluding data of the year. The Steering Committee discussed about the limits to be adopted in the data recovery policy, particularly taking into account the discussions raised after some proposals in Phase 2. It was recognised that although the ICCAT rules are very precise for Task I data, they do not define a minimum level of sampling for Task II data by fishery. This fact makes problematical a precise definition of the policy to be adopted for GBYP data recovery. The Coordinator provided some examples of data sets which are collected and provided according to the general rules under Task II, which are not very useful for scientific purposes. It was very clear that GBYP cannot pay for data that have been collected under national sampling schemes by ICCAT CPCs to fulfil their Task II obligations. It was also clear that many data are not usually provided to ICCAT even though they may be collected. This is because they are collected by various entities on their own costs and for various purposes. The Steering Committee recommended that a reasonable policy for GBYP is to limit the data recovery to data collected in previous years, excluding the data of the year. This policy would thus make a clear distinction between data recovery (which is a legitimate task under this part of the GBYP, and paying for the collection of data which are the responsibility of the CPCs (such as Task II). The Steering Committee also recommended that the focus in these cases should be on the last two decades and particularly for those data which could be directly used for stock assessment purposes, such as CPUEs or Task II data for fisheries poorly represented in the ICCAT bluefin tuna data base. At the same time, the Steering Committee recommended the GBYP Coordinator to contact the chair of ICCAT Sub-Committee on Statistics in order to initiate an exercise among all CPCs for establishing a minimum level of sampling for the provision of Task II data for bluefin (eventually this exercise could be extended to all species under the competence of ICCAT) and for eventually defining, in agreement with the scientists concerned, a minimum level of sampling coverage to be officially adopted by the ICCAT.

## First Meeting of the Joint Tuna RFMO Technical Working Group on By-Catch

## Data collection and harmonization

- The Working Group agreed that there should be minimum data standards, with data fields that are collected across all RFMOs with a view to allowing interoperability.
- All members of RFMOs are encouraged to improve the quality of data collection system to improve fisheries and by-catch assessments.
- All members of RFMOs are strongly encouraged to share data or information within RFMOs collected from observer and log book programs for the purposes of by-catch management and research.
- The Working Group will prepare a short report on data harmonization using all existing data forms from all tuna RFMOs by December 31, 2011. To facilitate this process, the IATTC forms will be circulated for a comparison with the other tuna RFMOs.
- Noting that there is a working group to be convened between IATTC and WCPFC on observer data harmonization, including by-catch, the Working Group recommends involving the other tuna RFMOs at this workshop.
- Seabird identification: the tuna Secretariats will provide ACAP with existing seabird identifications, and ACAP will develop a standardized identification guides. The drafts of the identification guides will be reviewed by the Working Group working group and Tuna RFMO working groups.
- Shark identification: the Working Group, with WCPFC and ICCAT taking the lead, will harmonize guidance for shark identification, in collaboration with the IUCN shark specialist group and others.
- Sea turtle identification: the Secretariats will provide the Working Group Chair with the materials currently in use for turtle identification so these can be harmonized and distributed to all tuna RFMOs.
- The Working Group should consider a process to develop harmonized marine mammal identification guides for the fisheries for which they are not available.

## Blue Marlin Stock Assessment Meeting and White Marlin Data Preparatory Meeting

- The Group recommended on the need to stress that CPCs should report Task I and Task II for Inter-sessional meetings by the deadlines provided by the Secretariat.
- The Group recognized the important new catch estimates of blue marlin from FAD fisheries of Martinique and Guadalupe and recommended that detail of estimation be presented as an SCRS document in the next species group meeting. The Group also recommended that other Caribbean countries with FAD fisheries report detail specific billfish catches.
- The Group encouraged the Secretariat to reach out to other RMFO in the Greater Caribbean to explore sharing data pertinent to ICCAT fisheries.
- The Group strongly recommended that the Commission provide additional funding (50K Euros) to the Enhanced Billfish Research Program for a genetic study in order to accelerate the data acquisition and analysis for separating white marlin from spearfishes to be undertaken in the immediate future.
- The Commission should require the reporting of catches of white marlin and roundscale spearfish separated.

## Addendum 4 to Appendix 7

## Response to the Resolution by ICCAT to Establish a Working Group on Sport and Recreational Fisheries [Res. 06-17]

In 2006, the Commission resolved that the SCRS should establish a Working Group to evaluate sport and recreational fishing activities. The Working Group would:
a) Examine the biological and economic impact of recreational and sport fishing activities on ICCAT managed stocks and assess the level of harvest.
b) Based on available information, identify approaches for managing the recreational and sport fishing activities in ICCAT fisheries.
c) Report the results of deliberations to the Commission and, as appropriate, propose recommendations for next steps to manage the recreational and sport fishing activities in the Convention area. CPCs shall report prior to the Working Group meeting the techniques used to manage their sport and recreational fisheries and methods used to collect such data.

With regard to item (a), the group recognized that recreational and sport fishing activities can have considerable biological and economic impact on ICCAT managed stocks. Furthermore, these impacts are not currently estimable due to a general lack of data.

With regard to item (b), the group recognized that the evaluation of suitable management measures requires reliable statistics be reported by all CPCs with non-trivial recreational and sport fisheries, and would be further improved by concomitant socio-economic data. The group recommended enhanced efforts by CPCs to collect and report such information.

With regard to item (c), the CPCs that attended the group made reports on their sport and recreational fishing activities, and the techniques used to collect data and manage these activities. These reports have been compiled, and are summarized below.

Taking into account the need to improve stock assessments by obtaining reliable estimates of total removals (harvest + dead discards) of ICCAT managed stocks; the Committee reiterated its following recommendation:

1. In order to develop appropriate estimates of harvest and dead discards by recreational and sport fishing activities, the SCRS recommended that each CPC:
a) Identify the "universe" of recreational fishing participants.
b) Sample that universe with appropriate coverage to allow estimation of total removals with sufficient accuracy and precision.
c) Produce or obtain estimates of release mortality to facilitate the quantification of fish released alive that subsequently die due to interaction with fishery.
2. The Committee concluded that sufficiently accurate and precise estimates of total recreational removals require CPCs to collect the following information through national and/or regional sampling programs. This data would be retained by CPCs, but used to develop the estimates of total recreational removals that are reported to ICCAT. The following should be considered minimum standard practices. These are the essential components for estimation of Task I and Task II data to meet reporting obligations.
a) Catch by species
b) Length/Weight of landed fish
c) Discards by species
d) Length/Weight of discarded fish
e) Disposition of discards (e.g. released alive and likely to survive, released alive but unlikely to survive, discarded dead, used for bait).
f) Location and time of fishing trip
g) Estimates of release mortality by species

The Group acknowledged that some CPCs have already developed successful sampling programs, and currently use data collected by these programs to report recreational Task I and Task II statistics to ICCAT. Several of these programs were identified by the group, and the methodologies were discussed. These issues will be further taken up at a future meeting of the Working Group on Stock Assessment Methods.

## REPORT OF THE MEETINF OF THE SUB-COMMITTEE ON ECOSYSTEMS

(Madrid, Spain - September 27-30, 2011)

The Meeting was held at the ICCAT Secretariat on September 27 to September 30, 2011. Mr. Cleo Small (BirdLife International) and Mr. Anton Wolfaardt (ACAP) volunteered to serve as rapporteurs.

## 1. Review of new scientific information

The Sub-Committee discussed and made recommendation regarding these documents. This discussion can be found in SCRS/2011/204.

Document SCRS/2011/150 provided an updated review of seabird by-catch mitigation measures for pelagic longline fisheries, undertaken by the Seabird By-catch Working Group of the Agreement on the Conservation of Albatrosses and Petrels (ACAP) in August 2011. The review includes the scientific evidence in support of the effectiveness of each mitigation measure, recommendations on appropriate combinations of measures, along with recommended technical specifications, monitoring requirements, and research needs.

Document SCRS/2011/151 presented a summary of the ACAP best practice advice for mitigating seabird bycatch in pelagic longline fisheries. Currently, no single mitigation measure can reliably prevent incidental mortality. The most effective approach is to use simultaneously weighted branchlines, night setting and bird scaring lines. It is recommended that these three measures should be applied in high risk areas such as the high latitudes of southern hemisphere oceans, and lower to mid-latitude fisheries of both the northern and south east Pacific, to reduce the incidental mortality to the lowest possible levels. Other factors such as safety, practicality and the characteristics of the fishery should also be recognised. ACAP best practice advice on bird scaring lines is that vessels $>35 \mathrm{~m}$ use two bird scaring lines, one on each side of the longline. For vessels $<35 \mathrm{~m}$, a single bird-scaring line, using either long and short streamers or short streamers only, has been found effective.

Current recommended minimum standard for branchline weighting configurations are:

- Greater than 45 g attached within 1 m of the hook or;
- Greater than 60 g attached within 3.5 m of the hook or;
- Greater than 98 g weight attached within 4 m of the hook.

On the basis of the evidence currently available, ACAP does not currently recommend the following as seabird by-catch mitigation options: line shooters, olfactory deterrents, hook size and design, side-setting, the use of blue-dyed bait and bait thaw status.

Document SCRS/2011/187 assessed the impact of the Uruguayan pelagic longline fishery on populations of albatrosses and petrels. The paper applied Productivity and Susceptibility Analysis (PSA) and the concept of "Potential Biological Removal" (PBR). This two-step approach allowed an estimate of the relative impact of the Uruguayan pelagic longline fleet for most of the populations or species of albatross and petrel that have high association with this fishery. Of 15 species addressed, 11 were fully evaluated, and a ranking of risk was obtained. The concept of PBR was applied to the eight most at risk species. The assessment found that the impact of fishing on populations could not be straightforwardly presumed from their by-catch rates. The results indicate that great albatrosses (Diomedea spp) and Atlantic yellow-nosed albatross Thalassarche chlororhynchos were more affected than the species caught in highest numbers by the fishery (i.e. black-browed albatross Thalassarche melanophrys and white-chinned petrel Procellaria aequinoctialis). Wandering albatross Diomedea exulans from South Georgia would be the population most affected by the Uruguayan fleet. This work should be seen as a case study of the fisheries operating in the southwestern Atlantic, particularly over part of the Brazil Malvinas Confluence (BMC). Considering the fishing effort that several pelagic longline fleets expend over the region of the BMC, this paper highlights that some populations of albatross and petrel are likely to be seriously affected.

Document SCRS/2011/198 presented seabird distribution maps based on seabird tracking data, interaction maps between longline fishery effort and seabird distribution, and data on the distribution of by-catch CPUE of seabird species in the South Atlantic, based on Japanese by-catch data, to identify by-catch hotspots. Tracking data indicate highest concentrations of the seabird breeding distribution in the area between $5-10 \mathrm{~W}, 35-40 \mathrm{~S}$, and 35-

40S, $10 \mathrm{~W}-15 \mathrm{E}$, and also $35-60 \mathrm{~S}$, $55-65 \mathrm{~W}$ during non-breeding. The available by-catch data confirm the distributions shown by the tracking data but there are exceptions in each species and degree of concentration of seabird distribution did not necessarily agree with the degree of CPUE in each species. The degree of interaction data was low level for the latitude 40-45S while CPUE of by-catch data was quite high. Interaction data showed concentration for latitudes $25-40 \mathrm{~S}$ longitudes $55-40 \mathrm{~W}$, where there is no by-catch data. It was suggested that three methods should be integrated to define the hotspot. Distribution of by-catch CPUE in albatrosses was high especially off South African waters and in the south-eastern Indian Ocean. Thus, there two area and the SW Atlantic would be considered as risk area for seabird by-catch, and it is necessary to introduce appropriate mitigation measure there.

Document SCRS/2011/201 reported the results of a study to estimate seabird by-catch by Taiwanese vessels in the Atlantic. Sixty one trips with 6,181 observed sets on Taiwanese longline vessels in the Atlantic Ocean from March 2004 to February 2008 were used to record the interaction between seabirds and longline fisheries. At least twenty eight species of seabirds were sighted, including two species in the north, fifteen species in the tropics and thirteen species in the South Atlantic. Eight species were albatrosses, the group of greatest conservation concern. 198 seabirds of eight major species were caught and 23 were live-released. The major bycatch species included yellow-nosed albatross, black-browed albatross, wandering albatross, spectacled petrel and southern giant petrel in the southern Atlantic Ocean. Major by-catch areas were $20^{\circ} \sim 40^{\circ} \mathrm{S}, 10^{\circ} \mathrm{W} \sim 15^{\circ} \mathrm{E}$ and $35^{\circ} \sim 45^{\circ} \mathrm{S}, 45^{\circ} \sim 55^{\circ} \mathrm{W}$. The nominal by-catch per thousand hooks ranged from 0 in the North Atlantic Ocean to 0.064 in the Southeast Atlantic Ocean. The observer coverage rate was too low for an accurate estimate of seabird by-catch in the northern Atlantic Ocean. In the tropical area, the level of observer coverage was high and indicated the seabird by-catch rate was low with low risks for seabirds. As for the South Atlantic Ocean, bycatch rates were influenced by the number of birds sighted and location using generalized additive models (GAMs). Total ICCAT pelagic longline effort was used in the final GAM to predict total by-catch in the South Atlantic Ocean. The predicted annual by-catch number with the bootstrapped $95 \%$ confidence interval was from 3,446 to 6,083 per year by pelagic longline fleets from 2004 to 2008 . The study highlights the need for all pelagic longline vessels operating south of 20 S to use bird scaring lines and other mitigation measures in order to reduce seabird by-catch. Continued collection of those data could provide information on the effectiveness of the current conservation measures. For future research and conservation, more international cooperation on research and data sharing is critical to ensure the sustainability of marine ecosystems and fisheries.

Document SCRS/2011/206 presented a proposal by Japan for the application of seabird by-catch mitigation measures in the South Atlantic. This paper is thoroughly described in the document SCRS/2001/204. Unfortunately, the Sub-Committee could not properly evaluate this paper because it dealt with policy issues, rather than a scientific evaluation.

## 2. Tuna RFMO Joint By-catch Technical Working Group

The Sub-Committee discussed the outcomes of the first meeting of the Joint By-catch Technical Working Group (JBTWG), which was a one-day meeting held on 11 July 2011 during the KOBE 3 Meeting. The Sub-Committee reviewed the general recommendation for the standardization and harmonization of data collection and the list of research priorities and discussed their relevancy to ICCAT. The Sub-Committee also produced a list of research recommendations of high importance in the ICCAT fisheries. This discussion and is summarized in SCRS/2011/204.

## 3. Ecosystem considerations

A National Scientist from the United States presented progress made in describing the Oxygen Minimum Zone in the tropical Atlantic Ocean. This feature has expanded since the 1960s resulting in a reduced proportion of the Atlantic Ocean possessing sufficient dissolved oxygen for high-oxygen demand species such and yellowfin tuna and blue marlin. The expansion of this feature (both in depth and surface area) has implications for stock since it may alter catchability and/or carrying capacity as the fish become compressed in the surface waters where the dissolved oxygen remains sufficient.

## 4. Recommendations

Given current ICCAT requirements of a minimum of 5\% observer coverage, and the need to collect and report data for a number of by-catch species, the SC-ECO recommends the development and implementation of capacity building programmes to improve sampling protocols, observer training and species identification (e.g. through identification guides or sending photos and samples to experts).

It is suggested that this report be cited in either of the following manners: ICCAT, 2012. Report for Biennial Period, 2010-11, Part II, ......pp.; or (Author), (Title of paper). In ICCAT, 2012, Report for Biennial Period, 2010-11, Part II, (pages).

[^0]:    ${ }^{1}$ Production model (Logistic) results represent median and $80 \%$ confidence limits based on catch data for (1950-2009) and the joint distribution of bootstraps using each of three alternative combined indices.
    ${ }^{2} 80 \%$ confidence limits, MSY and replacement yield rounded to 100 t .
    ${ }^{3}$ Reports for 2010 reflect most recent data but should be considered provisional. All other quantities in the table were calculated during the 2010 assessment.

[^1]:    ${ }^{1}$ Reports of catches for 2010 should be considered provisional, particularly for the West Atlantic.
    ${ }^{2}$ Although this time-area measure was implemented to reduce mortality on bigeye juvenile tuna, a total area closure has the expected effects on all the tropical tuna species.

[^2]:    ${ }^{1}$ Reference points estimates based on 2011 assessment. Median range and 80\% CI calculated for the whole range of the 8 base cases.
    ${ }^{2}$ Reference points estimates based on 2009 assessment. 95\% CI around the reference points were based on estimated 2007 standard errors in the North stock.
    ${ }^{3}$ Estimated with length converted catch curve analysis, taking M as a proxy for $\mathrm{F}_{\text {MSY }}$.

[^3]:    ${ }^{1}$ Approximated as the average of long-term yield at $\mathrm{F}_{0.1}$ that was calculated over a broad range of scenarios including contrasting recruitment levels and different selectivity patterns (estimates from these scenarios ranged between $29,000 \mathrm{t}$ and $91,000 \mathrm{t}$ ).
    ${ }^{2}$ The Committee decided, on the basis of current published literature, to adopt $F_{0.1}$ as the proxy for $F_{\text {MSY }}$ instead of $F_{\text {MAX }}$. $F_{0.1}$ has been indeed shown to be more robust to uncertainty about the true dynamics of the stock and observation errors than $\mathrm{F}_{\mathrm{MAX}}$.
    ${ }^{3}$ References to $\mathrm{F}_{\mathrm{MAX}}$ are given for the same ratios in parentheses for comparison purposes.
    ${ }^{4}$ The recruitment levels do not impact $\mathrm{F}_{2009} / \mathrm{F}_{0.1}$.

[^4]:    ${ }_{2}^{1}$ As estimated during the 2000 (Anon. 2001) and 2002 (Anon. 2003) assessments.
    2010 yield should be considered provisional.
    ${ }^{3}$ Catch ${ }_{\text {recent }}$ is the average longline catch for 2000-2004.
    Estimate of total removals obtained by the Committee.
    ${ }^{5}$ Range of estimates were obtained in the previous assessments, but recent analyses suggest that the lower bound for white marlin should be at least 600 t .

[^5]:    ${ }^{1}$ Results from Bayesian production model with informative priors. These results represent only the uncertainty in the production model fit. This range underestimates the total uncertainty in the estimates of MSY.
    ${ }^{2}$ Some countries have domestic regulations.
    ${ }^{3}$ Provisional estimate. The final figure, after discounting $1,100 \mathrm{t}$ of Maroc (see footnote in SAI-Table 1) would be 1,671 t .

[^6]:    Maroc 2010 catches of $1,100 \mathrm{t}$ (reported by mistake as SAI) will be revised to 0 t .

[^7]:    1 Base Case production model (Logistic) results based on catch data 1950-2008.
    2 Provisional and subject to revision.
    ${ }^{3} 80 \%$ bias corrected confidence intervals are shown.
    4 Provisional and preliminary, based on production model results that included catch data from 1970-2008.
    5 As of 29 September 2010.

[^8]:    ${ }^{1}$ Estimated catch used in the 2008 assessments (Anon. 2009b).
    ${ }^{2}$ Task I catch.
    ${ }^{3}$ Range obtained from BSP (low) and CFASP (high) models. Value from CFASP is SSB/SSB ${ }_{\text {MSY. }}$
    ${ }^{4}$ Range obtained from BSP (high) and CFASP (low) models. Value from CFASP is SSB/SS ${ }_{\mathrm{B} 0}$.
    ${ }^{5}$ Range obtained from BSP (low) and CFASP (high) models.

[^9]:    ${ }^{1}$ Estimated catch used in the 2008 assessments (Anon. 2009b).
    ${ }^{2}$ Task I catch.
    ${ }^{3}$ Range obtained from BSP (low) and CFASP (high) models. Value from CFASP is SSB/SSB ${ }_{\text {MSY }}$
    ${ }^{4}$ Range obtained from BSP (low), ASPM, and CFASP (high) models. Value from CFASP is SSB/SS ${ }_{\mathrm{B} 0}$
    ${ }^{5}$ Range obtained from BSP (low) and CFASP (high) models.
    ${ }^{6}$ Range obtained from BSP (high) and CFASP (low) models.

[^10]:    ${ }^{1}$ Estimated catch allocated to the northeast stock area.
    ${ }^{2}$ Range obtained from BSP (high) and ASPM (low) models. Value from ASPM model is SSB/SSB ${ }_{\text {MSY }}$. The value of 1.93 from the BSP corresponds to a biologically unrealistic scenario; all results from the other BSP scenarios ranged from 0.29 to 1.05 .
    ${ }^{3}$ Range obtained from the BSP and ASPM models (low and high for both models).
    ${ }^{4}$ Range obtained from BSP (low) and ASPM (high) models. The value of 0.04 from the BSP corresponds to a biologically unrealistic scenario; all results from the BSP scenarios ranged from 0.70 to 1.26.
    ${ }^{5}$ In the European Union.

[^11]:    * Delegates who only participated in the Species Groups.

[^12]:    ${ }^{1}$ The Steering Committee noted that, in addition to the budgetary implication, any type of survey has serious scientific problems if the coverage will not include all the areas where the bluefin tuna spawning activity is usually occurring with the highest intensity, e.g., the far eastern Mediterranean Sea. If the new budget proposed or the permits to operate in these areas are not guaranteed, then the survey should be suspended. At the same time, the commitment for the aerial survey should be for a number of years sufficient to provide a reliable trend.
