### 5.2 BFT - ATLANTIC BLUEFIN TUNA

The primary efforts of the Committee have been directed at implementing the workplan outlined for 2020 under the current extraordinary circumstances. This workplan originally focused on two areas: a strict update stock assessment and the ongoing development of the Management Strategy Evaluation (MSE), and has had to be adapted to the limitations imposed as a result of the outbreak of COVID-19. The MSE process has been compromised by these abnormal circumstances because the time allocated for technical meetings had to be reduced for reallocation to BFT Species Group intersessional meetings. These have been needed to ensure the completion of the stock assessment update to provide advice on the 2021 TACs, which has become the primary priority of the Committee. The bluefin tuna MSE Technical Group continues with its progress in developing operating models ( OMs ) by examining a broader spectrum of conditioned OMs , and is well advanced towards recommending a final reference set (or "grid") of OMs.

Given these impediments, the MSE process will not be completed in time to provide TAC advice to the Commission in 2021 for 2022-2024 based on a management procedure (MP). Accordingly, the Committee recommends extending the MSE process for another year with a goal of completing the MSE process in time for the 2022 Commission meeting to provide TAC advice for 2023-2025. In the event of a further delay in the MSE process, the decision on TAC advice for 2023 will be determined at the 2022 SCRS meeting. The Committee advises that interfacing with the Commission for further input (Panel 2, Scientists and Managers meeting, etc.) will be required intersessionally during 2021, but only once the MSE work is sufficiently advanced. This is because these interactions will be most effective only once interim results from the MSE are available which are sufficient to convey the inherent trade-offs on which the final selection of an MP will need to be based. Multiple dialogue sessions will be required commencing in the second half of 2021 and through 2022, before the Committee provides final advice regarding MP selection at its 2022 annual meeting.

This year's assessments for both East BFT and West BFT were conducted as strict updates as proposed by the SCRS and then approved by the Commission in 2019. This in turn means that the Committee did not attempt to improve the assessment models by undertaking further analyses, so that the various reservations raised in 2017 concerning this assessment still remain. Furthermore, the models could not be adjusted to take full account of new data and information in ways which might have led to improved results. This leads to additional uncertainty in the results obtained, compared to the uncertainty associated with those reported to the Commission in 2017.

The Committee considered that the strict update assessment of the East stock did not provide reliable information on which to base TAC advice for 2021 which once more brings into focus the need to investigate alternative assessment models to the VPA. However, based on an analysis of the stock size indices, the Committee did not find any clear evidence of changes in stock biomass from 2017 to 2020 to support changing the current TAC (Rec. 19-04) for 2021 and 2022. For the West, the updates of the VPA and Stock Synthesis were informative and the Committee found evidence of stock decline and provides a range of options for 2021, 2022 and 2023 TAC advice.

## BFT-1. Biology

Atlantic bluefin tuna (BFT) have a wide geographical distribution but live mainly in the temperate pelagic ecosystem of the entire North Atlantic and its adjacent waters, for example the Gulf of Mexico, Gulf of St. Lawrence and the Mediterranean Sea. Historical catch information documents the presence in the South Atlantic (BFT-Figure 1). Electronic archival tagging information has confirmed that bluefin tuna can tolerate cold as well as warm water temperatures while maintaining a stable internal body temperature. Bluefin tuna preferentially occupy the surface and subsurface waters of the coastal and open-sea areas, but archival electronic tagging and ultrasonic telemetry data indicate that they frequently dive to depths of more than $1,000 \mathrm{~m}$. Bluefin tuna are a highly migratory species that seems to display a homing behavior and spawning site fidelity to primary spawning areas in both the Mediterranean Sea and the Gulf of Mexico. Evidence indicates that spawning in other areas, for example the vicinity of the Slope Sea off the Northeast USA and more recently the Cantabrian Sea, though the persistence and importance of these other areas as spawning grounds remain to be determined. Electronic tagging is also resolving the movements to the foraging areas within the Mediterranean and the North Atlantic, and indicates that bluefin tuna movement patterns vary by tagging site, by month of tagging and according to the age of the fish. The reappearance of bluefin tuna in historical fishing areas (e.g. Norway and, more recently, the Black Sea) suggest that important changes in the spatial dynamics of bluefin tuna may also have resulted from interactions between biological factors, environmental variations and a reduction in fishing effort.

The fisheries for Atlantic bluefin tuna are managed as two management units, conventionally separated by the $45^{\circ} \mathrm{W}$ meridian. However, efforts to understand the population structure through tagging, genetic and microchemistry studies indicate that mixing is occurring at variable rates between the two management areas.

The ICCAT GBYP, as well as national research programmes, have provided the basis for improved biological studies. Substantial progress has been made in estimating regional, time varying mixing rates for Atlantic bluefin tuna, using otolith stable isotope and genetic analyses. Research on the larval ecology of Atlantic bluefin tuna has advanced in recent years through oceanographic habitat suitability models. Direct age estimation, using otoliths and dorsal fin spines from both stock areas, have been calibrated between readers from several institutions resulting in stock specific age length keys and a new growth model for the western population. Otolith preparation and reading protocols have been updated to minimize bias in age estimation. In 2020 a substantial part of the GBYP on-going activities has had to be postponed or cancelled due to the outbreak of COVID-19. Following Rec. 18-02 parag. 28, a research study of growth in farms was launched in 2019 at five locations, and a new database will be created to integrate all the data from stereocamera measurements and harvesting operations. Additionally, a Sub-Group on growth of BFT in farms was established in 2020 within the BFT Species Group. This Sub-Group was created to ensure that the best scientific data would be provided to the Commission. Due to the timing of the harvesting operations, the first meaningful results will become available in 2021 (see SCRS/2020/129).

Currently, the Committee assumes for assessment purposes that eastern Atlantic and Mediterranean bluefin tuna contributes fully to spawning at age 5 . There are also indications that some young individuals (of age 5) of unknown origin caught in the West Atlantic are mature, but there is considerable uncertainty with regards to their contribution to the western stock spawning. Therefore, the Committee has considered two spawning schedules for the western stock; one identical to that used for the East and one with peak spawning at age 15 . However, the latest review of reproductive biology has shown that both the current vectors for spawning fraction at-age might be biased, and that the magnitude of that bias is unknown. Juvenile growth is rapid for a teleost fish, but slower than for other tuna and billfish species. Fish born in June attain a length of about $30-40 \mathrm{~cm}$ and a weight of about 1 kg by October. After one year, fish reach about 4 kg and 60 cm in length. At 10 years of age, a bluefin tuna is about 200 cm and 170 kg and reaches about 270 cm and 400 kg at 20 years of age. Bluefin tuna is a long-living species, with a lifespan of about 40 years as indicated by radiocarbon deposition, and can reach 330 cm (SFL) and weigh up to 725 kg . In 2017, the Committee revised the natural mortality assumptions, and adopted a single new age specific natural mortality vector for both stocks.

Important electronic and conventional tagging activity has been conducted for both juvenile and adult fish for several years in the Atlantic and Mediterranean by the ICCAT GBYP, National Programmes and NGOs. Contributions from e-tag data from all groups are supporting ongoing efforts to provide important insights into bluefin tuna stock structure, distribution, mixing and migrations, and are helping to estimate fishing mortality rates and to condition the MSE operating models.

## EAST BLUEFIN TUNA

## BFTE-2. Fishery trends and indicators -East Atlantic and Mediterranean

Reported catches in the East Atlantic and Mediterranean reached a peak of over 50,000 t in 1996 and then decreased substantially, stabilizing at around TAC levels established by ICCAT for the most recent period (BFTE-Figure 1). Catches between 2015 and 2019 (as of 18 August 2020) were $16,201 \mathrm{t}, 19,131 \mathrm{t}, 23,616 \mathrm{t}$, $27,757 \mathrm{t}$ and $28,760 \mathrm{t}$ for the East Atlantic and Mediterranean, of which, $11,360 \mathrm{t}, 13,163 \mathrm{t}, 16,401 \mathrm{t}, 19,600$ t and 19,434 t were reported for the Mediterranean for those same years (BFT-Table 1). The Committee has been informed of the existence of unquantified IUU catches which should be taken into account.

Available information has demonstrated that catches of bluefin tuna from the East Atlantic and Mediterranean were seriously under-reported between the mid-1990s through 2007. The Committee estimated that the realized total catch during this period was likely of the order of $50,000 \mathrm{t}$ to $61,000 \mathrm{t}$ per year, based on the number of vessels operating in the Mediterranean Sea and their respective catch rates. Since the 2017 assessment (Anon., 2018), these estimates (1996-2007) have been treated as the actual catches.

During the 2017 Stock Assessment meeting (Anon. 2018), the decision was made to use ten abundance indices up to 2015 (seven CPUE series and three fisheries independent indices). The 2020 updated stock assessment has included the indices used for the 2017 stock assessment which were updated up to 2018, with the exception of the larval index which was updated to 2017 (BFTE-Figure 2). The Committee anticipates that additional indices could be used for tracking the abundance of the stock (e.g. GBYP aerial survey).

CPUE indices (BFTE-Figure 2) have been affected appreciably by regulatory measures through changes to operational patterns, length of the fishing season and target sizes; thus it is difficult to distinguish the effect of these changes on CPUE index values from the effects of changes in abundance.

## BFTE-3. State of the stock

There have been considerable improvements in data quality and quantity over the past few years; nevertheless important gaps remain in the temporal and spatial coverage for detailed size and catch-effort statistics for several fisheries, especially in the Mediterranean before the implementation of stereo video cameras in 2014. However, inconsistencies have been found in the length frequencies for some of the purseseiner catches since 2014; these consequently require further revision.

The 2017 and 2020 assessment results from the VPA base case indicated that the spawning stock biomass (SSB) peaked in the mid-1970s after increasing initially, and then declined until 1991 and remained steady until the mid-2000s. From the late 2000s, SSB exhibited a substantial increase through to 2018 (BFTEFigure 3). This increase as estimated in 2020 was appreciably larger than for the 2017 assessment, and not confirmed by the updated indicators (BFTE-Figure 3). The uncertainty about the magnitude of the recent SSB increase estimated by the VPA is even higher than for the 2017 assessment due to considerable instability in the recruitment estimates. Recruitment estimates for 2008 onwards (BFTE-Figure 3) are noticeably higher than for the 2017 assessment, showing a reverse of the trend of those estimated in the 2017 assessment. This was seen to be of concern when projecting the VPA forward to provide advice based on short-term projections, as well as leading to concern that the model results were very sensitive to adding one additional year of data (i.e. they led to an estimate of a substantial overall increase in biomass with the addition of only the last year of data). Concerns also remain that the size composition of many eastern Atlantic and Mediterranean fleets is poorly characterized for a number of years before the implementation of stereo video cameras in 2014.

The estimated fishing mortality rates on the younger ages (i.e., average $F$ for ages 2 to 5 ) displayed a continuous increase until the late 1990s, and then showed a sharp decline to reach very low levels after the late 2000s (BFTE-Figure 3). This result is a consequence of the dramatic reduction in the catches of ages 2 to 3 in recent years in response to the new minimum size regulations implemented in 2007 [Rec. 06-05]. The trend of F in young ages was similar to that for the 2017 assessment. For the oldest fish ( F at plus group for ages 10 and older) showed (BFTE-Figure 3) an initial decline from 1968 to 1973, and fluctuated slightly a little below 0.05 afterwards. This F increased in 1994 and continued increasing to 2005 ( $\mathrm{F}_{10+}=0.26$ ). This period (from the mid-1990s to the mid-2000s) evidenced the highest fishing mortality on larger fish. As noted in previous assessments, decreased TACs and catches resulted in substantial decreases in F10+ from the mid 2000s to 2010.

The current perception of the stock status depends on recruitment estimates which are highly unstable and is also closely related to the assumptions made about stock structure and migratory behaviour, which remain poorly known. Nonetheless, compared to 2017, the extra data now available confirm a recent stock biomass increase, although the magnitude of the increase remains difficult to quantify. $\mathrm{F}_{\text {CuR }}$ appears to be clearly below $\mathrm{F}_{0.1}$ ( $\mathrm{F}_{\text {CUR[2015-2017] }} / \mathrm{F}_{0.1}=0.426$ ), indicating a stock status determination of not overfishing.

## BFTE-4. Outlook

The Committee considers that recent recruitment estimates from the updated VPA assessment are highly uncertain and any short term catch advice based on $\mathrm{F}_{0.1}$ from the updated assessment would not be robust. Consequently, the Committee is not presenting new short-term projections. Due to the limited possibilities for improving the quality of the data, the Committee does not expect to be able to provide further clarity regarding future recruitment in 2021.

In 2018 and 2019, as requested in Rec. 18-02 the Committee evaluated whether the stock size indicators supported the TAC advice for $2019(32,240 \mathrm{t})$ and $2020(36,000 \mathrm{t})$, which arose from the 2017 assessment, and found that to be the case on both occasions. Evaluation of recent changes in these indicators in 2020 (SCRS/2020/128) has strengthened the support for Rec. 18-02 as these indicators did not indicate any substantial change since the 2017 assessment.

Consequently, based on an analysis of the updated stock size indices, the Committee finds no clear evidence which would warrant a change to the current TAC (Rec 19-04).

## BFTE-5. Effect of current regulations

Based on SCRS advice, in 2017 the Commission adopted Rec. 17-07 and updated it in 2019 with Rec. 19-04. It is too early since the associated TACs (2018-2020) were implemented to be able to evaluate their effect on the resource.

The Committee noted that reported catches are in line with recent TACs. However, the Committee has been informed of the existence of unquantified illegal catches of unknown magnitude.

The combination of size limits and the reduction of catch has certainly contributed to a rapid increase in the abundance of the stock.

BFTE-6. Management recommendations
The Committee noted that biomass indicators did not provide any evidence to alter the current management advice originally provided in 2017. The Committee points out that the projections from the 2017 advice showed that a constant catch of 36,000 tons from 2018 onwards reflects $\mathrm{F}<\mathrm{F}_{0.1}$ with a probability higher than $60 \%$ in 2021 and in 2022 (BFTE-Table 1).

Consequently, the Committee recommends that the 2020 TAC [Rec 19-04 para. 5] of 36,000 t be maintained for 2021 and 2022. However, the 2022 advice will be reviewed in 2021 based on updates of the abundance indicators as has been done in recent years.

BFTE-Table 1. The probabilities of $\mathrm{F}<\mathrm{F}_{0.1}$ for quotas from 0 to $50,000 \mathrm{t}$ for 2018 through 2022 under the recent 6 years (2006-2011) recruitment scenario, as estimated in 2017 stock assessment. Shading corresponds to the probabilities of being in the ranges of 50-59\%, 60-69\%, 70-79\%, 80-89\% and greater or equal to $90 \%$. Catches for 2016 and 2017 are assumed to be equal to the 2016 and 2017 TAC in all scenarios.

BFT-Figure 1. Geographic distribution of bluefin tuna catches per $5 \times 5$ degrees and per main gears from 1960 to 2017 (last decade only covers 8 years).

BFTE-Figure 1. Reported catch for the East Atlantic and Mediterranean from Task I data from 1950 to 2019 split by main geographic areas (top panel) and by gears (bottom panel) together with unreported catch estimated by the SCRS from 1998 to 2007 and TAC levels since 1998.

BFTE-Figure 2. Plots of the updated fishery dependent and independent indicators used for the East Atlantic and Mediterranean bluefin tuna stock. All indicators are standardized series and scaled to their averages. Indices denoted with "*" represent revised indices rather than strict updates of indices used in the 2017 stock assessment. The Spanish BB series was split in two series to account for changes in selectivity patterns, and the latest series was calculated using French BB data due to the sale of the quota by the Spanish fleet. The Japanese Longlines CPUE for the Northeast Atlantic (split in 2009/2010), the Morocco-Portugal Trap combined CPUE and French aerial survey index (split in 2008/2009) have been updated until 2018. The larval survey in the western Mediterranean was updated until 2017.

BFTE-Figure 3. Spawning stock biomass (in thousand metric ton), recruitment (in million), and fishing mortality (average over ages 2 to 5, and 10+) estimates from VPA base run in the 2020 stock assessment (blue) compared to the 2017 stock assessment (green) for the period between 1968 and 2015. The last years recruitments (dashed line: 2012-2013 for the 2017 stock assessment, and 2010-2015 for the 2020 stock assessment) were poorly estimated.

## BLUEFIN TUNA - WEST

## BFTW-2. Fishery indicators

The total catch for the West Atlantic peaked at 18,608 t in 1964, mostly due to the Japanese longline fishery for large fish off Brazil (that started in 1962) and the U.S. purse seine fishery for juvenile fish (BFT-Table 1, BFTW-Figure 1). Catches dropped sharply thereafter to slightly above $3,000 \mathrm{t}$ in 1969 with declines in longline catches off Brazil in 1967 and in purse seines. Catches increased to over 5,000 $t$ in the 1970 s due to the expansion of the Japanese longline fleet into the northwest Atlantic and Gulf of Mexico and an increase in purse seine effort targeting larger fish for the sashimi market. Catches declined abruptly in 1982 from close to $6,000 \mathrm{t}$ in the late 1970s and early 1980s with the imposition of a catch limit. The total catch for the West Atlantic, including discards, fluctuated without trend after 1982, reaching 3,319 t in 2002 (the highest since 1981, with all three major fishing nations indicating higher catches). Total catch in the West Atlantic subsequently declined steadily to $1,638 \mathrm{t}$ in 2007 and then fluctuated without pronounced trend. The catch in 2017 was $1,850 \mathrm{t}, 2,027 \mathrm{t}$ in 2018 and 2,305 t (as of 18 August 2020) in 2019 (BFTW-Figure 1).

The Committee notes that ongoing work conducted as part of the MSE process is evaluating the sensitivity to assumed stock of origin of the large catches coming from the South Atlantic. Future modelling considerations of these catches should consider that while these catches are currently assumed to be of Western stock origin the true stock of origin remains unknown.

The Committee notes that the TAC in the West has not been caught for the last 6 years. Based on information received, the Committee considers that this is not due to low stock abundance but rather to market and operational conditions.

The most recent (2020) stock assessment used 9 CPUE and two survey indices up to and including 2018 (BFTW-Figure 2). Indices presented here are strict updates of these indices except as denoted with an asterisk where slight modifications to the data or model structure have been made.

Several indices exhibit trends that may be indicative of environmentally driven changes in availability. As in 2017, the 2020 Stock Synthesis assessment reconciled the conflicting trends in some Canadian and United States indices under a hypothesis of environmentally mediated availability of fish to the two regions. The Canada Acoustic index experienced a very low value for 2018 and subsequently also for 2019; it appears that the index is in a state of transition, possibly due to environmentally driven changes in the spatial distribution of the fish or of their prey. For modelling the Committee chose to split the index for this assessment, which is equivalent to removing the 2018 datapoint from the assessment. Additionally, the USRR 115-144 index provided an extremely low value for 2018.

## BFTW-3. State of the stock

The SCRS cautions that conclusions from the latest assessment (Anon., 2020), using data through to 2018, do not capture the full degree of uncertainty in the assessments and projections. The various major contributing factors to uncertainties include mixing between the stocks, recruitment, age composition, age at maturity, and indices of abundance. As in 2017 the 2020 assessment also applied two stock assessment methods (VPA and Stock Synthesis) for management advice for the western stock. Models used in 2020 are strict updates of the 2017 models, with some modifications to estimated recruitment specifications to better account for uncertainty in recent and future recruitment.

Previous stock assessments determined stock status based on MSY-related reference points using two alternative recruitment potential scenarios: a 'low recruitment' scenario and a 'high recruitment' scenario. The 2017 assessment did not provide management advice based on MSY reference points. Instead, the focus was on giving short-term advice based on an $\mathrm{F}_{0.1}$ reference point (taken to be a proxy for $\mathrm{F}_{\mathrm{MSY}}$ ) using recent recruitment and assuming that near term recruitment will be similar to the recent past recruitment (BFTWFigure 3). As in the 2017 assessment two spawning fraction scenarios (a young age at spawning, consistent with the eastern stock and older age of spawning with $100 \%$ spawning contribution at age 15) were considered in the assessment methods. Rather than presenting two series of spawning stock biomass (SSB) based on these two spawning fraction scenarios, total biomass is presented as this does not depend on which of these scenarios is selected.

Results from the VPA indicate quite similar biomass and recruitment trends to the 2017 model. Biomass decreased sharply between 1974 and 1981 (BFTW-Figure 4), followed by more than two decades of stability (at about $50 \%$ of the 1974 biomass) across the turn of the century, and then by a gradual increase from 2004 to $60 \%$ of the 1974 biomass in 2018. Recruitment was high in the early 1970s, but subsequently fluctuated around a lower average until 2003 when there was a strong year class (BFTW-Figure 4). Recruitment has shown a downward trend since 2004, with recent (2010-2015) recruitments quite low. The three additional years (2013-2015) remain low with some of the lowest estimated recruitment in the time series.

Stock Synthesis gave a longer time series view of the population, (BFTW-Figure 4), capturing the higher recruitments estimated in the 1960s (though this is dependent on the assumption that the catches in the west were primarily of western rather than eastern origin fish). In 2017 the Stock Synthesis models estimated higher biomass than the VPA, but in 2020 the updated Stock Synthesis model and VPA estimates now are similar in magnitude for the overlapping period 1979-2015 (BFTW-Figures 3-5). Total biomass in 2015 was $14 \%$ of biomass in 1950 and $36 \%$ of biomass in 1974. Similar to VPA, Stock Synthesis estimates a mostly declining recruitment trend since 2003 with a slight increase in 2014-2016, though these recent increases are considered not to be well informed by data.

Though numbers of age 9+ fish are at or above 40-year peaks (BFTW-Figure 5) for both models, the numbers of age 6-8 year old fish is estimated to be at the lowest in the last 40 years due to low recent recruitments.

The Committee notes that further work is being conducted as part of the GBYP to collect more data on mixing, movement and stock of origin. These data are being incorporated into the Management Strategy Evaluation whereby they should help refine understanding of stock mixing.

## Summary

Both sets of results from the VPA and Stock Synthesis were equally weighted to formulate advice. Current $F$ (average of 2015-2017) relative to the $\mathrm{F}_{0.1}$ reference point was 0.8 (VPA) and 0.84 (Stock Synthesis), indicating that overfishing is not occurring (BFTW-Table 1, BFTW-Figure 4). Under the updated models the current TAC (Rec. 17-06) is likely to have led to overfishing relative to Fo.1 beginning in 2018.

Management advice is based on a fishing mortality reference point to project short-term catches based on recent recruitments. $\mathrm{F}_{0.1}$ was considered a reasonable proxy for $\mathrm{F}_{\text {mSY }}$, although it can be higher or lower than $\mathrm{F}_{\text {MSY }}$ depending on the stock recruitment relationship, which in this case is poorly determined.

## BFTW-4. Outlook

In 1998, the Commission initiated a 20 -year rebuilding plan designed to achieve SSB $_{\text {MSY }}$ with at least $50 \%$ probability. As indicated above, the Committee did not use biomass-based reference points in formulating 2017 advice, nor in the 2020 update. The Committee is not evaluating if the stock is rebuilt because it has been unable to resolve the long-term recruitment potential. If an $\mathrm{F}_{0.1}$ strategy were to continue to be applied, over the longer term the resource would fluctuate around the true, but unknown, value of $B_{0.1}$ whatever the future recruitment level. The $\mathrm{F}_{0.1}$ strategy compensates for the effect of recruitment changes on biomass by allowing higher catches when recent recruitment is higher and reducing catches when recent recruitments are lower. Under this strategy, biomass may decrease at times because the stock is above $\mathrm{B}_{0.1}$ or following lower recruitments.

The 2020 assessment indicates that recent (2012-2015) recruitments are low and further are lower than those estimated for the same time period in the 2017 assessment and from the averages assumed for the 2017 projections. In 2017 the population was projected to decline by $\sim 7.5 \%$ from 2017 to 2020 at the current (2020) TAC of 2,350 tons (Anon, 2019). However, based on the updated assessments, biomass is estimated to have actually experienced an $11.7 \%$ decline over the same time period (BFTW-Table 2). The expected changes in biomass under constant catch scenarios and one constant $\mathrm{F}_{0.1}$ scenario, are shown in BFTW-Table 3 and BFTW-Figure 6.

With three additional years added to the 2017 assessment (2016-2018), the overall biomass continues to decrease due to the 2003 year-class having passed its peak biomass together with below average recruitment in recent years. While the high numbers of 9 plus year old fish continue to contribute to catches, 6-8 year old fish that will form a large component of the next three year TACs are at very low abundance and hence lead to declining allowable catch in order to remain consistent with an $\mathrm{F}_{0.1}$ strategy where declining recruitment implies commensurate reductions in catch.

The Committee reiterates that the effects of mixing and management measures on the eastern stock remain a considerable source of uncertainty for the outlook of the western stock. Consequently, changes to assessment and management approaches that take explicit account of mixing are a high priority.

## BFTW-5. Effect of current regulations

The 2020 assessment estimates that the biomass has decreased by $11.7 \%$ (BFTW-Table 2) over the time period 2017-2020. The current TAC recommendation (Rec. 17-06) is set to end in 2020 with new TAC advice requested by the Commission. Under the updated models the current TAC is likely to have led to overfishing relative to F0.1 beginning in 2018 (BFTW-Figure 3). Roll-over of the 2020 TAC in Rec. 17-06 to 2021 is also expected to lead to overfishing (BFTW-Table 1)-and would result in a $6.4 \%$ reduction in the population biomass relative to 2020 (BFTW-Table 4).

## BFTW-6. Management recommendations

The Commission recommended total allowable catches (TAC) of 2,350 t in 2018, 2019 and 2020 (Rec. 1706). The Committee provides management options including the constant TAC scenarios shown in the Kobe II strategy matrix as well as a six scenarios for TAC advice. The TAC for each year, resulting impact on total stock biomass, percent change in biomass and probability of not overfishing associated with each scenario are shown in BFTW-Table 4 to illustrate trade-offs for the Commission to consider.

Scenario 1 corresponds to fishing at approximately $\mathrm{F}_{0.1}$ for 2021-2023. Scenario 2 is an approximate but not exact $60 \%$ probability of not overfishing in each year 2021, 2022 and 2023 . Scenario 3 corresponds to a strict rollover of the 2020 TAC for 2021 and then fishing at $F_{0.1}$ in 2022 and 2023. Scenario 4 is a stepwise reduction in TAC designed to achieve a similar biomass in 2023 as the $F_{0.1}$ strategy in 2023 and to end overfishing with $>50 \%$ probability by 2023. Scenario 5 and 6 are constant TAC scenarios derived from interpolating the Kobe Strategy matrix to achieve at least a 50 and $60 \%$ probability of not over fishing at any time over the three year period.

TAC should be reviewed annually by the Commission on the advice of the SCRS (which would be based on consideration of updates of the fishery indicators as well as intersessional work conducted to improve indices). This would permit the SCRS to, on any of those occasions, recommend that the next TAC be amended given sufficiently strong signals in the indicators.

## SUMMARY TABLE

Estimated recent fishing mortality rate (geometric mean of apical F for the period 2015 to 2017) relative to the F reference point, $\mathrm{F}_{0.1}$ (a proxy for $\mathrm{F}_{\text {MSY }}$ based on two recent recruitment specifications). Range across Stock Synthesis and VPA models are shown in parentheses.

BFTW-Table 1. Kobe II matrix giving the probability that the fishing mortality rate ( F ) will be less than the F reference point ( $\mathrm{F} \leq \mathrm{F}_{0.1}$, overfishing not occurring) over the next three years for alternative constant annual catches, based on results from the 2020 VPA and Stock Synthesis (combined as indicated in the main text).

| TAC | 2021 | 2022 | 2023 |
| ---: | ---: | ---: | ---: |
| 0 | $100 \%$ | $100 \%$ | $100 \%$ |
| 1000 | $100 \%$ | $100 \%$ | $99 \%$ |
| 1250 | $98 \%$ | $96 \%$ | $94 \%$ |
| 1500 | $91 \%$ | $86 \%$ | $80 \%$ |
| 1550 | $89 \%$ | $82 \%$ | $75 \%$ |
| 1600 | $85 \%$ | $76 \%$ | $67 \%$ |
| 1650 | $82 \%$ | $67 \%$ | $56 \%$ |
| 1700 | $75 \%$ | $57 \%$ | $45 \%$ |
| 1750 | $67 \%$ | $48 \%$ | $35 \%$ |
| 1800 | $57 \%$ | $37 \%$ | $27 \%$ |
| 1850 | $46 \%$ | $28 \%$ | $21 \%$ |
| 1900 | $38 \%$ | $23 \%$ | $17 \%$ |
| 1950 | $29 \%$ | $17 \%$ | $13 \%$ |
| 2000 | $23 \%$ | $14 \%$ | $12 \%$ |
| 2250 | $9 \%$ | $6 \%$ | $6 \%$ |
| 2350 | $6 \%$ | $5 \%$ | $4 \%$ |
| 2500 | $4 \%$ | $2 \%$ | $2 \%$ |
| 2750 | $1 \%$ | $1 \%$ | $0 \%$ |
| 3000 | $0 \%$ | $0 \%$ | $0 \%$ |

BFTW-Table 2. Relative change in total stock biomass relative to 2017 under alternative closest catch scenarios to 2350 t from the 2017 assessment (top rows) and depletion relative to 2017 from the 2020 assessments projected with either the realized or assumed TAC for 2018-2020, showing that the stock is now more depleted than original predicted. For both the 2017 and 2020 models, Stock Synthesis biomass is biomass as the beginning of the year and VPA represents mid-year biomass. For the 2020 model, Stock Synthesis and VPA projections come from averaging the deterministic model runs for 2 recruitment and 2 maturity specifications.

|  | TAC | 2018 | 2019 | 2020 |
| :---: | :---: | :---: | :---: | :---: |
| 2017 model | 2250 | $-1.7 \%$ | $-4.0 \%$ | $-7.2 \%$ |
| 2017 model | 2500 | $-1.7 \%$ | $-4.8 \%$ | $-8.7 \%$ |
|  |  |  |  |  |
| Realized or |  | 2027 | 2350 | 2350 |
| assumed TAC |  | $-2.6 \%$ | $-6.2 \%$ | $-11.7 \%$ |
| 2020 model |  |  |  |  |

BFTW-Table 3. Percentage change in total stock biomass at the middle of the year relative to 2020 under alternative constant catch scenarios from the 2020 assessment, based on the projections from Stock Synthesis and VPA, averaged across 2 recruitment and 2 maturity specifications. Stock Synthesis and VPA projections come from averaging the deterministic model runs.

| Catch | 2021 | 2022 | 2023 |
| :---: | ---: | ---: | ---: |
| 1000 | $-4 \%$ | $-4 \%$ | $-4 \%$ |
| 1250 | $-4 \%$ | $-6 \%$ | $-7 \%$ |
| 1500 | $-5 \%$ | $-7 \%$ | $-10 \%$ |
| 1550 | $-4.7 \%$ | $-7.6 \%$ | $-10.1 \%$ |
| 1600 | $-4.8 \%$ | $-7.9 \%$ | $-10.7 \%$ |
| 1650 | $-4.9 \%$ | $-8.2 \%$ | $-11.2 \%$ |
| 1700 | $-5.1 \%$ | $-8.5 \%$ | $-11.7 \%$ |
| 1750 | $-5.2 \%$ | $-8.8 \%$ | $-12.2 \%$ |
| 1800 | $-5.3 \%$ | $-9.1 \%$ | $-12.7 \%$ |
| 1850 | $-5.4 \%$ | $-9.4 \%$ | $-13.3 \%$ |
| 1900 | $-5.5 \%$ | $-9.8 \%$ | $-13.8 \%$ |
| 1950 | $-5.6 \%$ | $-10.1 \%$ | $-14.3 \%$ |
| 2000 | $-5.7 \%$ | $-10.4 \%$ | $-14.8 \%$ |
| 2250 | $-6.2 \%$ | $-12.0 \%$ | $-17.4 \%$ |
| 2350 | $-6.4 \%$ | $-12.6 \%$ | $-18.5 \%$ |
| 2500 | $-6.8 \%$ | $-13.5 \%$ | $-20.0 \%$ |
| 2750 | $-7.3 \%$ | $-15.1 \%$ | $-22.7 \%$ |
| 3000 | $-7.9 \%$ | $-16.7 \%$ | $-25.3 \%$ |

BFTW-Table 4. Scenarios for three-year TAC advice. Predicted yield ( t ), total stock biomass ( t ), \% total biomass change from 2020 and probability of not overfishing, by management scenario averaged across both VPA and Stock Synthesis. Scenarios 1 and 2 come from an approximation of a 50 and $60 \%$ probability of not overfishing in each year but did not quite achieve the desired intent in the time available. All TAC scenarios reflect running projections with the prescribed TAC to accurately estimate probabilities resulting from having taken the previous year's TAC shown below.

| Management Scenario | Predicted Yield ( t ) |  |  | Predicted (mid-year) <br> Total Biomass ( t ) |  |  | Percent Change in Total Biomass (mid-year) from 2020 |  |  | Probability of Not Overfishing |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 2021 | 2022 | 2023 | 2021 | 2022 | 2023 | 2021 | 2022 | 2023 | 2021 | 2022 | 2023 |
| 1. Approximate 50\% Probability of Not Overfishing or approximate Constant $\mathrm{F}=\mathrm{F}_{0.1}$ | 1831 | 1738 | 1678 | 22918 | 22000 | 21218 | -5.3\% | -9.1\% | -12.4\% | 49\% | 46\% | 44\% |
| 2. Approximate $60 \%$ Probability Not Overfishing | 1785 | 1684 | 1633 | 22940 | 22072 | 21342 | -5.2\% | -8.8\% | -11.8\% | 58\% | 58\% | 54\% |
| 3. Rollover in 2021 to $\mathrm{F}=\mathrm{F}_{0.1}$ | 2350 | 1685 | 1632 | 22647 | 21506 | 20778 | -6.4\% | -11.2\% | -14.2\% | 6\% | 50\% | 48\% |
| 4. 255 mt step 2021-2023 | 2095 | 1840 | 1585 | 22780 | 21681 | 20900 | -5.9\% | -10.4\% | -13.7\% | 15\% | 27\% | 56\% |
| 5.1630 t constant | 1630 | 1630 | 1630 | 23021 | 22257 | 21551 | -4.9\% | -8.1\% | -11.0\% | 83\% | 71\% | 61\% |
| 6. 1680 t constant | 1680 | 1680 | 1680 | 22995 | 22181 | 21424 | -5.0\% | -8.4\% | -11.5\% | 78\% | 61\% | 50\% |

(a)

(b)

BFTW-Figure 1. Historical catches of western bluefin tuna: (a) by gear type and (b) TACs agreed by the Commission (which are shown for comparison).

BFTW-Figure 2. Indices of relative abundance for western bluefin tuna. Indices denoted with "*" represent revised indices rather than strict updates of indices used in the 2017 stock assessment. Indices denoted with an "s" were used in Stock Synthesis and indices with a " $v$ " were used in VPA. The Canadian Acoustic index data point for 2018 was not used in the assessment models.

## Apical Fishing Mortality Relative to $\mathrm{F}_{0.1}$ Reference point

BFTW-Figure 3. Fishing mortality relative to the $\mathrm{F}_{0.1}$ reference point as estimated by VPA (red) and Stock Synthesis (blue) for the 2020 assessment. The $80 \%$ confidence intervals are indicated with dashed lines.
